The onset of hypertension is evidenced by the patient's giving vent to short, sharp coughs. This signal has been of decided value as a warning of impending danger. The giving of more than about 200 c.c. of blood after the occurrence of "the signal cough" may prove fatal.

Transfusion yields moderately good results in infectious and debilitating conditions. The best results are obtained in toxemias, in shock, in cases of hemorrhage, and in diseases of the blood, in which it is frequently of life saving value.

162 West Eighty-Fifth Street.

ABSTRACT OF DISCUSSION

DR. E. W. PETERSON, New York: Any one who has done a large amount of this work will encounter these miracles. As has been pointed out, whole blood administered by transfusion as a hemostatic is such. Most of my work has been with the citrated method, but I think just about as good results are obtained from the citrated method as from the modified.

DR. FRANK W. HARTMAN, Washington, D. C.: My experience has been with the citrate method. I want to ask Dr. Unger about these reactions, whether a reaction was really anything more than uncomfortable to the patient, and whether the results in the final stages were better than with the unmodified blood mixed with the whole blood.

DR. LESTER NEWMAN, Washington, D. C.: My experience has been entirely with citrated blood. I agree with Dr. Peterson as to some of the failures.

DR. E. LIBMAN, New York: To avoid difficulties resulting from errors in the agglutination tests, it is wise when citrate transfusion is to be done to make tests with citrated speci-

mens. My experience with transfusions in cases of infections leads me to believe that they act only as a supportive measure. In cases of infection, the blood itself is usually bactericidal. What we need are methods for developing tissue immunity. Some observers have been misled into thinking that transfusions act in a bactericidal fashion because the bacteria often disappear from the blood after transfusion. However, this usually only happens if there has been a reaction after the transfusion. When, in a case of general infection, a reaction occurs after transfusion, the blood is apt to become free of bacteria for a day or two. The same thing will happen, however, if you get a reaction after injecting a salt solution. In some interesting studies made in cases of streptococcus endocarditis by Dr. Epstein, with a colloidal preparation of iodine, the bacteria would sometimes disappear from the blood for three or four days, and then return. Too much stress cannot be laid on the proper examination of the donor. It is not sufficient to make the tests—the donor must be examined from head to foot. This is of the greatest importance in excluding all lesions of syphilis unaccompanied by a positive Wassermann reaction. To avoid the effects of putting in large amounts of blood, it is important to cut down the fluids before the transfusion is performed. In cases of cardiac disease, especially mitral stenosis, great caution must be used as regards the amounts of blood given. The cough symptom as described by Dr. Unger is very valuable. The two most valuable methods are the Unger and the citrate methods. The citrate method appears to cause more reactions than the Unger method; in febrile cases, both methods are apt to produce chills and rises of temperature. In patients in very poor condition from toxic diseases, in which it is important to avoid a chill, the Unger method may be preferable. It is necessary that studies be made as regards the effects of and the contraindications to the use of transfusions in cases accompanied by various renal conditions. I know of two instances in which a citrate transfusion caused a temporary blocking of the kidney. It may be found that the same will occur in cases of renal disease when other forms of transfusions are used.

FOREIGN BODIES WITHIN THE EYEBALL*

JOHN O. McREYNOLDS, M.S., M.D., LL.D.
DALLAS, TEXAS

The literature on this subject has been so thoroughly reviewed by Würdemann, Ramsey and others that we may pass at once to the practical consideration of the various points that naturally arise for decision and action; and if we can succeed in so presenting the most important problems as to develop a full discussion, the result would be the ripened conclusions of American ophthalmology.

The whole matter, so far as the patient and the surgeon are concerned, can be resolved into the three primary questions:

1. What are the location and character of the foreign body?
2. What are the proposed measures of relief?
3. What will be the probable immediate and remote results?

LOCATION AND CHARACTER OF FOREIGN BODY

The answer to the first question involves a careful analysis of many circumstances and facts. Is the foreign body actually within the globe, or has it been withdrawn through the point of entrance, or has it gone entirely through the globe and found lodgment in the

postocular tissues? These questions are fundamental and yet may involve perplexing difficulties. The media may be so clouded by hemorrhage or corneal, lenticular or vitreous opacities that a satisfactory examination with the ophthalmoscope or with other instruments for direct inspection would be impossible. The foreign body may be of such a nature as to offer no resistance to the roentgen rays, or it may be so minute as to cast no perceptible shadow, or it may be non-magnetic and hence would give no response to the magnet or sideroscope. Here it is that the history may be of the greatest value, as some illustrative cases will emphasize.

We have all many times encountered injured eyes in which it was difficult to determine whether the foreign body was just within or just without the sclera, especially when the foreign body was evidently driven with considerable force, or was small, or was not impervious to the roentgen rays. Injuries of this kind are, frequently, bird shot injuries with intra-ocular hemorrhage; and, fortunately, the roentgen ray will usually be sufficient to determine the location. Occasionally the presence of postocular hemorrhage with proptosis will point to traumatism behind the globe and will confirm the roentgen-ray findings. In such cases, if the traumatism is not excessive we may avail ourselves of the ten-day period of probation admissible in all cases of eye injury without risk of sympathetic ophthalmia, and many illuminating features may develop. The postocular hemorrhage after a short time may show as a dark discoloration about the lids, and the swelling will subside and the inflammatory features recede to such a degree that we may safely persist in our efforts to save an eye that might have been sacrificed under the suspicion of a retained foreign body. As a rule, small aseptic bodies, passing entirely through the eyeball and lodging in the retro-bulbar cellular tissue, may be allowed to remain, and they generally give rise to no future trouble.

Some regard may be paid to the propelling force and to the distance traversed by the foreign body before entering the eye as bearing on the question whether it has lodged within the eye. If it is within the globe and cannot be extracted, an enucleation or evisceration will be the probable result sooner or later. If it has passed entirely through the globe, the prognosis will depend largely on its path. If it enters the sclera posterior to the ciliary region and in its passage has produced very little hemorrhage and no injury to the macular region, the result may be favorable as to the preservation of vision. If, however, it passes through the lens or ciliary body with much laceration of the tissues, the primary wound will probably be followed by inflammatory changes leading to loss of the eyeball.

Having determined the location of the foreign body to be within the globe, we must next consider the toleration for such bodies by the different anatomic structures, which vary greatly in this respect, and also the chemical and bacteriologic character of the foreign body. Generally, those tissues which are most abundantly supplied with nerves and blood vessels are the least tolerant of foreign invasion. The iris and ciliary body especially resent the presence of an intruder, while the lens, if slightly wounded, may indefinitely accommodate a sterile particle of small magnitude. The posterior segment of the retina and choroid may, by throwing around the foreign body a protecting cov-

* Read before the Section on Ophthalmology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

ering of plastic exudate, bear the intruder for a considerable time, while the vitreous with its sluggish reaction may allow the foreign body to float freely in its mass. The chemical nature of the foreign body greatly influences its tendency to produce reaction; thus, glass may be harbored kindly, while copper will provoke a prompt and decided response. But the most important feature in the character of a foreign body relates to its bacteriologic status. All portions of the internal structures of the eyeball offer good media for the propagation of various micro-organisms, but many of these bodies before entering the eye have been sterilized by heat, and a study of this factor may be helpful in arriving at a wise conclusion. Much depends on the virulence of the organisms that may be introduced with the foreign body. If an active infectious process is once established within an eye containing a foreign body, the prognosis is more unfavorable. I have, however, seen cases of vitreous infection, demonstrated as such by microscopic findings, in which a rather extensive intra-ocular operation succeeded in mechanically removing all of the infected tissue, with the preservation of the globe.

With reference to the size, we might say that the larger foreign bodies involve greater hazard by virtue of the traumatism which they inflict on their entrance, although the promptness and ease with which they are generally removed would be factors in their favor.

It has so happened in my experience that eyes wounded with glass do not as a rule contain the pieces of glass. The wounds are frequently badly lacerated, but may yield a fairly good result.

As bearing on the nature of a retained foreign body, the presence of a distinct siderosis is quite characteristic of a ferruginous body which has been undergoing partial or complete absorption.

MEASURES OF RELIEF

The method of removing a foreign body from the eye depends entirely on its character, size and location. A natural division as to character would be magnetic and nonmagnetic, the former being more easily removed because of the availability of magnetic influence. Much has been written about the kind of magnet that is most efficient. The dictum of Haab that "He who has the strongest magnet will get the best results" must be taken with some modification.

The facility with which the magnet may be manipulated, thus bringing the electrode into the most favorable approximation to the foreign body, must constitute a most important factor. My personal preference is for the improved Sweet magnet, which has the usual power requisite for attracting magnetic bodies, and in addition its electrode can be brought in contact with the foreign body in any part of the globe. The Haab magnet, the Victor magnet, the intrapolar magnet and other large magnets are especially applicable to those cases in which it is sought to remove the foreign body through the anterior chamber in accordance with the views advocated by Haab.

Since the introduction of the more accurate methods of localization by the roentgen ray, the relative value of the medium sized magnets as compared with the giant magnets has been advanced. I think no one now would prefer the giant magnet in the case of large foreign bodies, on account of the violent force developed, which might do harm to uninjured structures; but it has some advantage in those cases in which the

foreign body has not been accurately located and in which it is situated in the anterior segment of the globe. Even in the case of foreign magnetic bodies in the vitreous, after a scleral incision, the point of the giant magnet may be applied to the opening of the wound, either alone or in conjunction with magnetized probes, forceps or scissors; and if unsuccessful, this procedure may then be followed by the use of the Sweet magnet, which has the advantage of greater ease in accurate manipulation.

It is a matter of considerable importance to decide wisely as to the route to be adopted in the removal of a foreign body, whether by the anterior or the posterior route. And it must be admitted that there are advantages in both methods, and the difficulty is in discriminating between the two in each individual case. My own experience has emphasized the safety and practicability of removing foreign bodies through a scleral incision whenever the foreign body is easily accessible by this route. I have not seen retinal detachment at the seat of the incision follow such a procedure, and when detachment has occurred it was due to the inflammatory process induced by the presence of the foreign body and by the original traumatism.

On account of the dangers of iridocyclitis, with a possible transferred ophthalmitis, I have a profound respect for the anterior segment of the eyeball, and would prefer to employ no procedure which would add anything to the traumatism in this region. Unless the conditions are such that the foreign body can be smoothly extracted by this route, I should prefer to invade the posterior segment of the globe rather than the ciliary zone.

RESULTS

The immediate and remote results must have regard, not only to the injured eye, but also to the fellow eye. In general terms, we might say that the immediate result in the injured eye will be favorably influenced by the following factors: accurate localization, the early removal of the foreign body, the minimum of traumatism by the flight of the missile and the subsequent operative procedure, the noninvolvement of the ciliary body, the lens and the macula region, and the negative chemical and bacteriologic character of the foreign body.

It must be remembered that the victory has not been won when the foreign body has been brilliantly extracted from the interior of the globe. We must still await, some times through weeks and months and years, the final processes of degeneration, retinal detachment and clouded media which may bring but grief and pain for promised joy.

We must remember not only that the insidious danger of sympathetic ophthalmia lurks in the presence of the foreign intruder, but also that the seeds of disaster are sometimes sown in its pathway, springing up into that fateful fruitage which brings total blindness with its blighting brood of unavailing regrets.

ILLUSTRATIVE CASES

The purpose of this report of Cases 1, 2 and 3 is to emphasize some important features pertaining to the localization, the extraction and the final result in cases of exceedingly minute foreign bodies within the globe. We have always recognized the full significance of the retention within the eyeball of all foreign bodies of a magnitude capable of being determined by the ordinary methods; but some special consideration might be given

to the behavior of those particles so extremely small as to cast no shadow, after the skillful application of the most powerful and efficient roentgen light.

As to localization, I might say that we have felt since the introduction of the Sweet method that all magnetic metallic bodies could be certainly located with accuracy; but I have encountered some recent cases that

Fig. 1 (Case 3).—Roentgenographic appearance of the eye before (left) and after (right) attempt at extraction of the foreign body. The first picture showed a distinct shadow of a foreign body located as shown in the diagram, Figure 2. The second picture, taken some time after the attempt at removal with the giant magnet, shows no foreign body, but the patient had a complete secondary cataract with a marked degree of sclerosis.

show that some particles of this kind may elude the roentgen ray and still be clearly perceived by the ophthalmoscope and extracted by the giant magnet. The cases were examined by roentgenologists of unquestioned ability and extensive experience, who have repeatedly rendered me the most valuable assistance in the localization of very minute masses of foreign matter within the globe, and I esteem it a pleasure to bear testimony, unreservedly, to their patience and skill.

CASE 1.—Mr. R. of Weatherford, Texas, came to me with the history of a slowly developing cataract in the right eye, beginning some weeks after the supposed receipt of an injury to the eye four months previously. He had been carefully examined by a competent ophthalmologist who reported traumatic cataract from concussion, a condition which we all frequently have occasion to observe.

On my first examination with lenses of high power, I discovered on the temporal side of the sphincter pupillae a minute opening through the iris tissue, in diameter equal to the cross-section of a cambric needle. This opening at first appeared dark in color, like a speck of pigment, but on lateral illumination I could see the opaque lens substance through this minute aperture. I then applied the giant magnet directly to the corresponding area of the cornea, and the lens and iris were observed to advance slightly. I described the occurrence to the roentgenologist, and requested a close examination of the anterior segment of the globe. After repeated trials, no foreign body could be definitely located. I then invited the roentgenologist to be present at the proposed extraction of the steel. An incision was made along the corresponding arc of the limbus, and through this incision I passed a pair of fine steel iris forceps, and up to the minute opening in the iris above described. Then, while I held very firmly to the forceps, the tip of the giant magnet was brought in contact with the forceps at the point of entrance of the latter into the anterior chamber. Then the current was turned on and the magnet and attached iris forceps were gently withdrawn from the eye, bringing out of the lens and through the needle hole in the iris an exceedingly delicate piece of steel. With the most accurate jeweler's scales available the foreign body was declared imponderable, but was estimated to weigh approximately one-thousandth of a carat. Its length was 2.2 mm., its breadth was 0.2 mm. and its thickness was that of the finest thread. The accident occurred while the patient was standing a few feet

from one of his employees, who was using a chisel on a piece of marble. The vision was not at first impaired, and the pain and reaction were insignificant; but at the time of my examination, the lens was completely opaque. It is interesting that so slender and so delicate a piece of metal should be driven such a distance and with such force as to become completely embedded in the lens and yet remain unbroken by its impact.

The indications are that a cataract extraction at any subsequent time will secure for the eye useful reading vision.

CASE 2.—Mr. L. A. of Dallas was operated on in conjunction with my partner, Dr. Seay. The history clearly traced the injury to a blow which the patient struck on a chisel, and the vision became at once impaired, but gradually cleared up, so that a minute piece of metal was distinctly seen with the ophthalmoscope near the center of the vitreous chamber. The trabeculae of the vitreous were broken down in the lower segment of the vitreous, thus allowing limited movement of the metal when the eyeball was quickly rotated.

The roentgen ray was called into requisition for confirmation, as a question had arisen as to whether this movable mass was of metal or of pigment. No shadow whatever was developed, and the magnet failed to make any impression on the mass. But the ophthalmoscopic picture was so conclusive that we made an incision in the region of the equator and between the external and inferior rectus muscles. Through this scleral opening we passed into the globe delicate steel iris forceps until their points approximated the foreign mass. Then we applied the tip of the giant magnet to the forceps at the point of entrance of the latter into the vitreous chamber. The current was then turned on and the magnet and forceps gently withdrawn from the eye, bringing along a very minute, polyhedral piece of steel. The eye was again examined with the ophthalmoscope, and a piece of metal was discovered in the central area of the vitreous. So we reinserted the forceps and applied the magnet as before;

when they were withdrawn from the eye, the remaining piece of steel was found attached to the distal extremities of the forceps.

The ophthalmoscopic examination showing no more foreign material, a double con-

Fig. 2 (Case 3).—Diagrams showing the location of the foreign body.

unctival flap was carried by mattress sutures over the scleral wound, and the usual surgical precautions followed. After a lapse of more than ten months, the media are still clear and the vision is normal.

CASE 3.—Mr. G. H. of Groesbeck, Texas, was struck in the eye, July 5, 1915, by a piece of steel, causing pain and immediate reduction of the vision. The vision then improved; and when the patient was seen, July 6, by my partner, Dr. Seay,

the vision was 20/40. The roentgenogram at that time showed a distinct shadow of a foreign body 1 mm. in diameter and situated 12 mm. back of the center of the cornea. Dr. Seay applied the giant magnet to the point of entrance of the steel without producing any distinct impression (Figs. 1 and 2).

An operation for extraction was then advised, but the patient preferred delay because of the existence of useful vision and the absence of pain.

Fig. 3 (Case 4).—Roentgenographic location and appearance of the foreign body in the eye.

Recently the patient presented himself with a complete secondary cataract and with a marked degree of siderosis, converting a light blue iris into a rusty brown, with brownish deposits on the lens. The roentgenogram by the same expert as before failed to show any foreign body whatever. We accordingly extracted the opaque lens so that now through the moderately clear media we can confirm the roentgenographic findings of complete absence of any foreign body, and useful vision has been secured for the injured eye.

The indications are that the piece of iron had undergone complete solution in the vitreous, and the resulting salts of iron had become deposited in the various intra-ocular tissues. The case is worthy of record as bearing on the question of the solubility of metals in the humors of the eyes and on the further question of the influence of these resulting salts on the transparency of the lens, the substance of which was not stained by the salts of iron but was completely protected by the capsule. The lenticular opacity was evidently due, not to direct injury but to nutritional changes in the uveal tract. The final result in all cases must await the action of those gradual processes of vitreous contraction and retinal detachment which may supervene even after the lapse of many months to mar the satisfaction of our best achievements.

Cases 4, 5 and 6 were extensive injuries, and they serve to illustrate the possibilities in such cases even in the presence of definite infection.

CASE 4.—Master C. C. of Greenville, Texas, aged 14 years, exploded a copper shell by striking it with an ax. A piece of the margin of the shell from which the ball and powder had been extracted was driven into the eyeball. This occurred, May 2, 1911. The wound in the lid was repaired by Dr. C. E. Cantrell, who sent the patient to Dallas for operation, which was performed, May 3, after an accurate roentgenogram had been made by Dr. J. M. Martin. The weight of the piece of copper was 3 grains, and the dimensions were 5 by 9 mm. The location was 3 mm. below the horizontal plane of the cornea, 19 mm. to the temporal side of the vertical plane of the cornea, and 8 mm. back of its center. The roentgenogram and diagram (Figs. 3 and 4) are herewith presented. The wound in the sclera began at the upper and outer portion of the limbus and extended through the ciliary region for one-eighth inch; the pupil was irregular and vision reduced to the perception of fingers at 3 feet. A new incision was

made through the sclera below the external rectus over the situation of the foreign body, which was extracted with forceps, together with the contiguous portions of the vitreous, which had become opaque and slightly yellow from the inflammatory process, which was infectious in character as shown by the microscope. Both wounds were then freed from the adjacent uveal tissue, and closed with a double layer of conjunctiva secured in position by mattress sutures. An interesting feature is that the infectious process in the vitreous did not extend, evidently because the infected portions were freely removed with the foreign body embedded therein. The normal form and comfort of the eyeball have been maintained, and the patient has since graduated with honor at the Virginia Military Institute and has played his part in the military affairs of his country.

The chief lesson taught by this experience is the value of freely removing infected vitreous surrounding a retained foreign body rather than allowing it to remain within the globe. It is simply an extension of the general surgical principles so well established during the war, but which perhaps have not been so widely accepted with reference to the vitreous humor, which we have sometimes been too uncompromising in preserving.

CASE 5.—Ben McC. of Cleburne, Texas, was struck in the eye by a piece of steel, Dec. 25, 1917, which was accurately located by Dr. Bond of Fort Worth and Dr. Martin of Dallas as being 7 mm. above the horizontal plane of the cornea, 3 mm. to the temporal side of the vertical plane, and 13 mm. back of the center of the cornea (Fig. 5). The dimensions were 1.5 by 7 mm. Operation was performed, December 28. A scleral incision was made over the site of the foreign body,

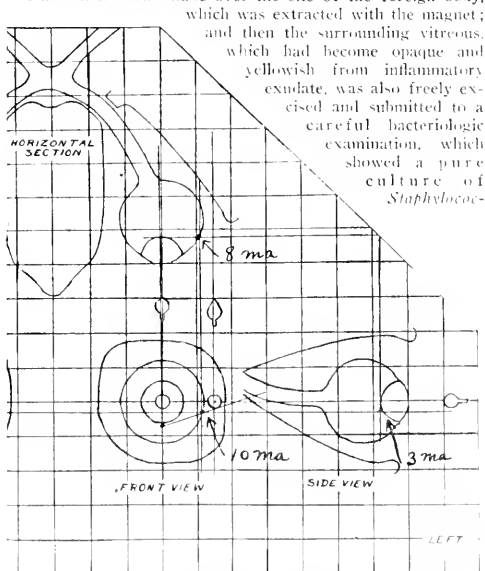

Fig. 4 (Case 4).—Diagrams showing the location of the foreign body in three planes.

ing albus, as also did the piece of steel and an excised piece of the injured iris. The wound was closed by double layers of conjunctiva held in position by mattress sutures, a method which I have used for many years with great satisfaction. It is conveniently and aptly designated as the double breasted coat conjunctival covering. Its advantages were fully described by Dr. Lee Martin Francis in a paper before this

section some years ago. The wound healed without any unfavorable manifestations, and presents a reasonably satisfactory appearance, as indicated by the photograph (Fig. 7).

The method employed in excising the opaque infected vitreous consisted in grasping the tenacious exudate with forceps and gently drawing it through the wound, catching successively new holds on the infected tissue with curved iris forceps, somewhat after the manner of drawing a well with a rope, continuing the procedure as long as opaque

Fig. 5 (Case 5).—Diagrams showing the location of the foreign body in three planes.

vitreous presented. My feeling in the matter is that no good can result from leaving in the eye injected material, and that the small loss of vitreous involved is easily compensated for by the improved bacteriologic status of the eye in the process of healing. I will add in this connection that in all injured eyes, when I am confronted with the possibility of transferred ophthalmitis during my efforts to save a severely injured eye, I am in the habit of adopting a measure suggested by our distinguished confrere, Dr. Harold Gifford—saturating the system with salicylates before any sympathetic manifestations appear.

CASE 6.—Mr. B. of Dallas County was, in conjunction with another man, arranging to blast some rock in excavating for a cistern. The discharge of giant powder occurred prematurely, killing instantly the comrade of the patient, and inflicting on the latter the injuries now to be described. When the patient was brought to me two days after the accident, the left globe had been reduced to a perfectly disorganized pulp which admitted of no rational procedure but emeciation, which was accordingly performed. The right globe was perforated in two places by lacerated wounds, and an examination revealed the presence of three pieces of rock within the eyeball, one piece being about half as large as the nail of the little finger. The eye was considerably inflamed and evidently infected, as shown by the character of the discharge. But as the fellow eye was utterly lost and the only possibility of vision depended on the eye not totally gone, I decided to make the most of a poor opportunity. So, after as thorough disinfection of the injured organ as the circumstances would permit, I made an incision into the globe to an extent greater than half of the circumference of the cornea, in order to be

able to reach the scattered fragments of rock which had lacerated and had become embedded in the iris. Unfortunately, the difficulties encountered by the surgeon in dealing with fragments of rock within the globe are much greater than in the case of steel bodies, because the latter can be extracted by the aid of various forms of the electromagnet. And fragments of rock are much more difficult to handle successfully than pieces of wood, because the increased weight of the former is such that when the globe is opened they tend to make a dive for the deeper regions of the vitreous. In this case it was necessary to remove large areas of the lacerated iris in order to be sure of the fragments of rock. The extraction of the rocks and the removal of the injured iris we accomplished by the combined use of hooks and forceps. After the operation the lids were kept closed with light compresses saturated in cool boric acid solution, and at frequent intervals instillations of a mydriatic were made and lotions of mild antiseptics employed. After a few weeks the patient was discharged from St. Paul's Sanitarium with ability to read ordinary type.

In Cases 7, 8 and 9, the foreign body was allowed to remain in the eye for a considerable time, and failed to respond to any measures but the intra-ocular application of magnetic electrodes.

CASE 7.—Mr. W. B. C. of Dallas was struck in the eye by a piece of steel which I present herewith, together with the roentgenograms (Fig. 8) taken in advance of the operation, which was performed eight weeks after the injury. The weight of the steel is 1_{100} carat, and the location was 6 mm. below the horizontal plane of the cornea, 6 mm. to the nasal side of the vertical plane of the cornea and 9 mm. back of its center. There was a circumscribed corneal opacity surrounding the track of the steel, and vision amounted to dim perception of fingers. The iris had closed up the anterior capsular opening produced by the entrance of the steel into the lens, and had thus restricted the access of aqueous to the lens substance with consequent limitation of the opaque zone. An incision along the limbus was made and the iris drawn away from the lens with iris forceps, exposing the point of entrance of the steel. An electrode of the improved Sweet magnet was introduced into the opening thus disclosed. The current was turned on and the magnet with the attached piece of steel removed. The eye, which had continued to be irritable before the operation, now quieted down completely, and a subsequent cataract extraction should result in useful vision.

Fig. 6 (Case 5).—Roentgenographic appearance of foreign body and scar.

This illustrates the toleration of the lens for foreign bodies and the action of the iris in limiting the extent of lenticular opacity by preventing the free access of aqueous to the lens substance. The application of the giant magnet to the cornea failed to develop any response, while the direct contact with the electrode of the Sweet magnet was effective, showing that even in the case of foreign bodies located in the anterior seg-

ment of the eye, the giant magnet applied according to the method of Haab cannot always secure the best result.

CASE 8.—Mr. J. C. A. of Clarendon, Texas, was struck in the eye with a piece of steel three years previously, and the foreign body was located by a roentgenogram near the pos-

Fig. 7 (Case 5).—Appearance of patient after operation.

terior pole of the eye embedded in the retina. As the lens was cataractous, it was extracted in the usual way and immediately an iron probe was passed through the corneal wound, through the pupillary space, through the vitreous, until its point was approximately in contact with the foreign body. Then the electrode of the giant magnet was applied to the probe at its point of entrance into the cornea, the current was turned on, and the magnet and probe gently withdrawn, together with the foreign body attached to the distal extremity of the probe. The eye healed without trouble and for some months retained useful vision, after which the patient passed out of observation.

The history of this case shows the feasibility of utilizing the pupillary space as a doorway through which we may safely reach the vitreous when an extraction of the lens is necessary. I think this route for the introduction of magnetized probes has not been widely employed; but it offers an avenue that is worthy of our consideration.

CASE 9.—Mr. E. D. of Dallas, Texas, aged 35, was struck in the eye in 1905 by a piece of steel, and the vision was lost at once. *Confrères* failed to locate any foreign body, and the eye remained fairly quiet for three years, when photophobia and other manifestations of sympathetic weakness in the good eye developed, while the injured eye was cataractous and showed a marked degree of siderosis.

The piece of steel was located (by the roentgen ray) near the posterior pole, embedded in the retina. The lens was extracted and an iron probe passed through the corneal wound, through the pupillary space, and through the vitreous until it approximated the foreign body. The electrode of the giant

magnet was applied to the probe at its entrance into the anterior chamber, the current was turned on and then the magnet, probe, and foreign body were gently withdrawn. The healing process was uneventful and the patient retained useful vision for several years, when the degenerative changes progressed to the point of abolition of vision in the injured eye, although the fellow eye has been free from indications of sympathetic involvement.

CASE 10.—Lieutenant S. of Love Field, an aviator, was referred to me by the post surgeon, Major Earthman, within a few hours after the receipt of an injury which was occasioned by the impact of some foreign body driven by the tremendous force of the propeller. Examination showed that a small foreign body about the size of a duck shot had penetrated the upper lid and had entered the globe in the superior segment of the ciliary zone. There was a prolapse of uveal tissue, and blood filled the anterior chamber, with immediate loss of vision. Apparently a foreign body was either within the eyeball or had passed on through into the retrobulbar region. The roentgen ray showed absolutely nothing, but this could have been explained by the hypothesis that the foreign body was not impervious to the roentgen rays. Nevertheless, as the danger of sympathetic involvement could not reasonably be apprehended within ten days, it was safe to use conservative measures, so the protruding uveal tissue was removed and the usual surgical measures employed for a few days, when the hemorrhage became absorbed and the lens was found to be clear, the fundus normal and the vitreous presented a few floating remnants of the previous hemorrhage, which subsequently became completely absorbed. The eye was free from pain or suspicious inflammatory changes, and will probably remain a safe and useful organ of vision, the degree at present being 20/30.

What evidently occurred at the time of the injury was that the foreign body which struck the eye had a sharp point, which permitted a partial penetration which was limited by the size of the foreign body and was immediately spontaneously withdrawn, thus presenting a punctured wound without the retention of a foreign body within the globe. This illustrates the necessity for the utmost conservatism in differentiating retained foreign bodies from punctured wounds presenting many circumstances and appearances that might obtain in either condition.

In connection with extensive wounds of the cornea produced by the entrance of foreign bodies, something

Fig. 8 (Case 7).—Roentgenographic appearance of the eye and orbit just prior to the operation for foreign body, which was performed eight weeks after the injury.

might be said concerning the closure of these wounds after the foreign bodies have been removed.

CASE 11.—The procedure can be illustrated by the case of a young woman, Miss M. N., whose eye was cut wide open by glass from an explosion in the chemical laboratory of the Southern Methodist University in Dallas. The irregular, gaping wounds extended entirely across the cornea; and as normal approximation was impossible, the problem developed of securing a closure of the wounds.

This was accomplished by providing a bridge of bullar connective, swung like a hammock across the cornea and retaining its original attachment at either extremity. This conjunctival bridge, carrying its vascular supply was allowed to remain in contact with the wounds until the healing process was completed and then it was carefully dissected away, leaving only linear scars to mark the situation of former gaping wounds.

ABSTRACT OF DISCUSSION

Dr. WILLIAM M. SWETT, Philadelphia: Dr. McReynolds has so fully covered every phase of the subject of foreign body injuries of the eyeball that there is nothing new to add. It is now generally recognized that the first consideration is to determine whether the body which caused the injury has lodged within the eyeball or orbit, and if within the eye, its position and approximate size. Many injured eyes have been lost in the past by delay in making the diagnosis of a foreign body in the globe, local measures being employed for a considerable period until the metal or other material causing the traumatism was so covered with exudate that attempts at extraction failed. I have always favored the scleral incision for the removal of steel from the vitreous chamber. As most of the particles are at or posterior to the equator of the globe, the body has a shorter distance to travel than if brought around the lens. It is only in the few instances in which the metal is of small size, and with no irregular surfaces to be caught in the anterior uveal tissues, that I have drawn the metal into the anterior chamber.

My experience in retinal detachment following extraction agrees with that of Dr. McReynolds. I have not found the separation at the site of the incision in the sclera but in other portions of the vitreous chamber. In the cases in which detachment occurs, I believe it is due to the contraction of the newly formed inflammatory lesions at the point in the retina or choroid where the parts have been injured by a fairly large body, or, in instances in which a smaller body has remained imbedded for several days or weeks, to the traumatism which has followed the drag of the magnet in loosening the metal from the exudation in which it was imbedded. With the apparent trivial character of so many of these foreign body injuries to the patient and his friends, the ultimate results as to vision are rather unsatisfactory; and yet I fail to see any possible improvement in our present methods of diagnosis or operative procedure. One third of all cases in which there has been perforation of the globe by a foreign body are lost; some from primary infection, some from inability to remove the body, and a larger number from late iridocyclitis. Where extraction has been successful, only a few secure useful vision. Our endeavors, therefore, must be in the direction of earlier diagnosis of a retained foreign body in the eyeball and its prompt removal. This will come with the recognition by the general profession of the serious nature of perforating wounds of the eyeball in workmen in industrial establishments, and earlier consultation with the specialist. It has been my practice in all perforating wounds of the eyeball, especially those of large size, to cover the opening with a conjunctival flap. When an incision is to be made in the sclera for the extraction of steel from the vitreous chamber, a cut is first made in the conjunctiva, the membrane undermined for a short distance, and the edges of the cut held apart by two threads. After extraction of the steel the edges of the cut conjunctiva are closed over the incision in the sclera. I have seen a few cases in which the roentgen rays failed to give a shadow of a foreign body that was in the eyeball. A thin foreign body may be so situated that the edge of the metal is toward the tube, and only a faint line of shadow is cast that may be lost in the shadow of the orbital bones. If the examination points to a probable foreign body in the globe not shown in the first roentgenograms, it is advisable to make additional plates, with the tube in different positions, so that a shadow is secured on the plate free from the shadow of the bones of the orbit.

Dr. R. H. T. MAXX, Texarkana, Ark.-Texas: Several years ago I began some experimental work to see if the dangers

from operations on the interior of the eye could not be much lessened by increasing the air pressure on the outside, thus equalizing the pressure of the interior of the globe and preventing the flow of vitreous from the eye during an operation for the removal of foreign bodies in the vitreous chamber. These experiments have so far been carried on in the thoracic chamber apparatus, at the Lenox Hill Hospital, in New York City. The first steps of the experiments have consisted in trying to ascertain whether both operator and the eye should be in the air tight chamber, or whether the operator should be in the air tight chamber and the patient on the outside of the chamber, with the air pressure exerted against the anterior segment of the eye alone. It seems from the present limited experiments which have been performed that this is along the lines which will have to be adopted, because the pressure in the eye may increase as rapidly as the pressure on the outside which prevents the equalization of the pressure. It is perfectly feasible for the operator, without any difficulty, to remain within the air tight chamber with the pressure increased to the pressure of the normal eye, which is 25 mm. of mercury. The increased blood pressure in the interior of the eye is somewhat offset by the hard coats of the eye, and this will be of considerable assistance in retaining the vitreous within the eye itself. I think that the air pressure can be exerted on the anterior segment of the eye during operations, thereby preventing the loss of vitreous and the collapse of the eye. If this can be done, it will not only simplify very much the removal of foreign bodies from the vitreous chamber, but also render easy other operations on the eye where there is danger of losing the vitreous. The reason why all the vitreous does not escape now is because the pressure becomes equal, and with the patient looking up gravity prevents it from all escaping.

Dr. JOHN GREEN, St. Louis: The possibility of a localized infection of the vitreous immediately surrounding the site of the foreign body suggests one objection to the anterior route. Given an infected foreign body in the vitreous, with the point of entrance in the sclera the patient coming under observation soon after the accident, that method of extraction which, so far as possible, follows the track made by the entering foreign body, should be followed in its extraction. The adoption of any other route means the risk of infecting a previously uninfected track. It is as though we should streak an infected platinum loop along a previously untrekked surface of the culture medium.

Dr. EDWARD JACKSON, Denver: Many very interesting points have been brought out, and among them I wish to refer to one. The most common and dangerous failure of roentgen-ray localization of foreign bodies in the eye, which I have encountered, has been the report that the foreign body was outside of the eyeball, when it was really within it. I think that probably is due to the fact that sufficient allowance has not been made for the divergence of the rays used in localizing. The rays are always divergent. The amount of divergence depends especially on the distance it is from the eye. Most men using the diagrams which have been prepared for this purpose are not at first inclined to take that into account. Such diagrams should have printed on them some reference to it. If the diagram represents the exact size of the eyeball, and is intended to represent in millimeters the exact position, there should be a table indicating the increase of dimensions, which would be caused by using the tube at six inches, eight inches, ten inches, etc. The printing of something of that kind on the diagram will call the attention of the roentgenologist and the surgeon to the fact that the negative obtained shows the part magnified.

Dr. W. M. SWETT, Philadelphia: On the charts for plotting the position of the foreign body, allowance is made for the divergence of the roentgen rays. If the body is of large size, it is customary to localize the two ends. A slight error is possible in foreign bodies at the posterior part of the vitreous, owing to the injured eye being larger or smaller than the diagrammatic eyeball of the chart, which measures 24 mm. Accuracy of localization depends on the determination of the distance of the indicating ball of the apparatus from the center of the cornea. If the roentgenographer fails

to carefully make the measurements the localization of the foreign body will be inaccurate.

DR. ALLEN GREENWOOD, Boston: I trust the few brief remarks I will have to offer will never again be applicable. Never again do we want to go through the experiences we have been through, but if, perchance, some of you are called on to do work such as was done in the last few years in France, you will find that handling these cases in the military organization is entirely different from the civilian method in many ways. In the hurry of work in mobile and evacuation hospitals, it is difficult to get roentgen-ray work done with accuracy and speed. Therefore, in removing foreign bodies the magnet, besides the work of removal, is of great service from a diagnostic standpoint and it should be thus used. If a foreign body is demonstrated it possibly can be brought into the anterior chamber and then removed with the smaller magnet. I would call your attention to the magnet we used most in France, which weighs nearly sixty pounds, the large one of Dr. Lancaster, which has practically the same pull as the giant Haab. The question of the removal of foreign bodies by the posterior route or by the anterior route, so-called, will probably never be settled as some men would prefer one and some the other. Both methods are useful but both have limitations. I extracted most of the foreign bodies I saw through the posterior route, only removing very small ones by the anterior route.

I want to add a word in regard to the use of the conjunctival flap. Some of you have seen Military Manual No. 3 in which you will find advocated the use of the conjunctival flap and the hammock flap of Dr. N. C. Reynolds, which have been used for covering the central wounds of the eyes and with excellent results.

DR. LEE M. FRANCIS, Buffalo: I want to emphasize what Dr. Sweet brought out, that is, taking pictures of the suspected foreign body from more than one direction. In one case in Base Hospital No. 115, in which we selected an anterior route as the roentgenogram gave us the idea that it was a small one, instead of having a round body, we had a splinter of steel four millimeters in length. We should have used the posterior route and we would not have lost it. We must be sure of the third dimension of the foreign body.

DR. GEORGE S. DERBY, Boston: During eight months of the time I was in France I had the opportunity of working in the principal eye base at Boulogne. At least 500 foreign bodies in the eyes were treated. I had an opportunity of talking with a number of French surgeons who were treating this class of cases. The British are strongly in favor of the extraction by the anterior route, and that was the principal mode of operation in France by them. The French, however, used the anterior route in some cases and the posterior route in others. You may have a foreign body when there is no sign of a perforation, or none is visible, at least. Do not overlook that. It must not be thought because you have no sign of entrance that it is not there. The roentgen ray is a fine test, but the final test is the magnet. The giant magnet should be used in all doubtful cases. I believe small foreign bodies measuring less than one millimeter should be extracted by the giant magnet by the anterior route. The British used it for larger pieces. If you cannot get a small body in one sitting, try it again, either the same day or the following day. I have seen a number of cases where it was not brought forward until three or more trials, and then it was successfully extracted. Sometimes we are in doubt as to whether the foreign body is in the eye or has passed through the eyeball. Where the perforation is complete one gets an evident degree of proptosis of the eyeball, and this I believe is an excellent diagnostic sign.

DR. E. E. HOLT, Portland, Me.: When I presented my first series of cases of removal of foreign bodies from the interior of the eye to the American Ophthalmologic Society, more than thirty years ago, some of the members were sure that disastrous results would follow this practice. This series of cases, as well as the second series of cases presented to this society, and all of my subsequent cases, were followed as carefully as it was possible to follow their subsequent history without finding that this practice did lead to dis-

astrous results. The diagnosis of all my cases in the first two series of cases presented to the American Ophthalmologic Society was made from the circumstance of the accident, the size and location of the wound in the eye, electromagnet and the ophthalmoscope. When the foreign body could not be detected by the ophthalmoscope there was no more difficulty experienced in removing the metal than when it could be readily seen. When the wound was small or was located in the cornea, the metal was removed by making a flap of the conjunctiva and an incision into the eyeball in the inferior outer quadrant, using a medium sized hand magnet for its extraction. My experience teaches me that time is an element of the greatest importance in the successful removal of foreign bodies from the interior of the eye, there being much less reaction when it is removed on the same day of the accident than at any subsequent time. This is of so much importance that I should prefer to operate without a roentgen-ray examination if I could not get one right away after the case came under my care provided I was quite sure the foreign body was in the eye. As the essayist says "watchful waiting" will not do, something must be done to remove the foreign body from the eye if we are to treat these cases successfully. When my first series of cases was presented to the American Ophthalmological Society, some of the members expressed surprise that I should have so many more cases than the rest of the members. The explanation made at the time was that I began the practice of removing the foreign body from the interior of the eye, thus saving the eye with sight instead of removing the eye, as had been expected by all concerned, and insisted that it should be done at the earliest moment possible after the accident. This practice becoming generally known among those liable to these accidents, they lost no time in having it carried out at once. The reason why the other members of the society had so few cases at that time came from the fact that it was taught that when an eye was injured by metal penetrating it, in what had been designated the "dangerous zone," and the metal remained in the eye, the eye should be removed. This was done by the general surgeon. Thus the specialist did not see many of these cases. When, however, it became more generally known that a foreign body could be removed, thus saving the eye with sight, the specialist was consulted and he began to have cases commensurate with accidents of this nature.

DR. OLIVER TYNEXES, Chicago: For some years we had the first and only giant magnet west of the Allegheny Mountains, and in that time we have had a great number of injuries. We came to look on the giant magnet as being an infallible diagnostic instrument; but our delusion was dispelled, and not with a case tried once or twice, but frequently; not by one man, but by three of the most competent men in the profession, until we discovered that the roentgen ray disclosed what a giant magnet would not. And we are able to locate the pieces of steel with the roentgen ray that we could not with the giant magnet. I do not know why, but there are times when iron or steel is diamagnetized, and you will have that experience. With regard to the localization, it is very important. I can recall a case localized behind the globe which I did not disturb, and it got well with good visual acuity; but that case is a sad commentary on the neglect of treatment afterwards. In this case a foreign body had passed through the globe, injuring the lens, which was absorbed. Vision after several months with correction was 20/20. When next seen a quiet iritis had distorted the pupil, which interfered greatly with vision and 22/100 was the best that could be obtained until after the long use of scopalamine the vision was again brought to practically normal. On account of its position, no attempt was made to find out what the foreign body was. I think it was a shot, and is still posterior to the globe and doing no damage.

DR. JOHN O. McKEYNOLDS, Dallas, Texas: An important question arises as to the magnetic quality of various alloys of iron, and it is well known that a high percentage of manganese may render the iron non-magnetic and hence in such cases the magnet would be of no value either in diagnosis or in operation. One of the most difficult problems in connection with these cases is presented after the foreign body

has been successfully removed. It is this, how long are we justified in persisting in our efforts to save a seriously wounded eye? My own conviction is that if the eye is going to do any good this fact will be indicated within a period of three weeks and further delay may unnecessarily imperil the uninjured eye.

THE MAXIMUM PHYSIOLOGIC LYMPHATIC REACTION IN DEEPLY PENETRATING WOUNDS OF THE EYEBALL

E. L. JONES, M.D.

CUMBERLAND, MD.

While the deep tissues of the eyeball are among the body's structures most highly susceptible to infection from penetrating wounds, they have profited very little by the great principles of wound sterilization as developed by modern antiseptics, and eyes so injured are daily being removed, as compound fractures of extremities in the old days were followed by amputations to save the patient from death from sepsis. This is true because the delicate structures of the eye cannot stand any really efficient germicide. Nor can such be given free access to the seat of infection, nor can the parts be laid open for free drainage, nor can damaged tissues be cut away as in recent war surgery.

How, then, may this situation be altered for the better? The answer is to be found in exciting an abundant flow of lymph, which is nature's antiseptic and tissue restorer, and goes to every part of the eye that a germ can reach. There may be other ways of producing this reaction, but the one that I have employed for a number of years is a massive subconjunctival injection of mercuric cyanid in conjunction with certain other drugs, by which the subconjunctival spaces on the ball, and the loose tissues of the lids are speedily distended to their utmost with lymph, preventing in most instances the lids' being opened for several days, and often causing swelling even on the face. How much lymph circulates through the tissues is not known; but the amount which transudes out can easily be told by squeezing out a pad which has been on an eye for twenty-four hours, after having been wet with about 2 ounces of water. If to this be added nitric acid, it will curdle so that it is as dense as buttermilk.

In my experience, covering fifteen years, all manner of extensive and deep penetrating wounds, many attended by nonrecoverable foreign bodies, have healed with no signs whatever of infection, or of degeneration or damage aside from the initial injury. In a paper on "Foreign Bodies Within the Eyeball," read before the Section on Ophthalmology at the recent session of the American Medical Association, Dr. McReynolds¹ states that the victory has not been won when the foreign body has been brilliantly extracted, and anxious days of waiting in fear of sepsis follow. He speaks of the slow degenerative changes which may follow after months or years, including detachment of the retina.

It was said by Dr. Herman Knaapp, in the early days of giant magnet extraction, that these cases made a grand impression at first, but that many patients ultimately became blind. Mr. Gustavus Hartridge² says,

in discussing this subject before the Ophthalmological Society of the United Kingdom in 1915:

The patient appears to make an excellent recovery, and leaves the hospital with perhaps almost normal vision; months later the vision of the eye gradually fails, and on examination, a large detachment is found. I have seen dozens of cases in which a foreign body is removed from the back of the eye through the vitreous end this way.

Another prolific source of destruction, in my belief, is the organization and shrinking of profuse vitreous hemorrhage. It is my contention that all of these patients should be given the massive cyanid injection, which sterilizes the eye, furnishes lymph to repair damaged tissue, and promotes absorption of blood effused into the vitreous. Furthermore, the swelling of the conjunctiva closes and covers the wounds, and protects them from conjunctival secretions, serving the purpose of the double flap suture advocated by Francis, and the sliding flap operation recommended in the official Military War Manual No. 3 on ophthalmic surgery.

A number of oculists who have used the injection in cases of intractable diseases have found that it serves them well; let us hope it will be given the same trial in cases of deeply penetrating wounds, and the wounds attendant on magnet operations.

Dr. McWhinnie³ has detailed a series of phenomenal results from these injections, among them an extensive scleral wound made by a dirty fish knife, presenting a condition for which textbooks advise immediate enucleation, in which the eyeball and vision were saved by the injection. I have in sundry publications pleaded for the single massive injection instead of frequent small or salt water injections, and have had my beliefs confirmed by men who have used the plan advocated. The detractors are found among those who use the small or mild injection, and fail to excite the maximum physiologic lymphatic reaction.

A SECOND ATTACK OF SYPHILIS TWO YEARS AFTER THE FIRST

CURABILITY OF THE DISEASE *

JAY FRANK SCHAMBERG, M.D.

PHILADELPHIA

In view of the fact that the Wassermann reaction is not infrequently negative in the presence of indubitable evidence of active syphilis, in the minds of many, this query has arisen: "How can we ever be sure of the complete extinction of the disease?" Indeed, many physicians have expressed doubts as to its curability. It is important for the profession to have placed before it as much convincing evidence pointing to the radical extermination of the syphilitic infection as possible, in order that there may be developed a crystallized scientific judgment on this important question. There is every reason to believe that many patients treated intensively in the early primary stage are cured, for they commonly remained free of symptoms for years and repeatedly have negative blood tests. But these data do not amount to any constitutive evidence of cure.

² Hartridge, Gustavus, Tr. Ophth. Soc. U. K., 1915, Vol. XXXV, p. 175.

³ McWhinnie, New York M. J., 1917, 343 (Feb. 24) 1918.

* Read before the Section on Dermatology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

in the subjoined case, in which treatment was given after the secondary symptoms had developed, a definite cure took place:

REPORT OF CASE

A man, aged 23, contracted syphilis in June, 1917. During a drunken orgie, he and two companions collaborated with the same woman, and all three became infected. (The other two victims were treated by us for syphilis.) The patient, with a suspected chancre of the meatus, was first seen, June 21, in the hospital of the University of Pennsylvania, by Dr. Hollingsworth Siter. July 2, a macular eruption appeared on the body. An intravenous injection of neo-arsphenamin was given, and also some mercury by mouth. August 14, the patient presented himself at the University Hospital with headaches, inequality of the pupils and exaggerated patellar reflexes. The Wassermann reaction was positive. A second dose of neo-arsphenamin was administered.

PROTOCOL OF PATIENT WITH TWO ATTACKS OF SYPHILIS WITHIN TWO YEARS

6-21-17	Suspected chancre of meatus.
7-2-17	Macular eruption on body. Ulceration and induration about meatus.
7-2-17	Injections of neo-arsphenamin; also mercury by mouth.
8-14-17	Headaches, inequality of pupils. Exaggerated patellar reflexes. Enlarged cervical glands. Injection of neo-arsphenamin.
8-17-17	Wassermann positive.
9-9-17	Came under treatment at Polytechnic Hospital. Wassermann tests with three different antigens, +, +, +, and +, +, +.
9-22-17	Arsenobenzol brand of arsphenamin 0.6 gm.
9-23-17	Arsenobenzol brand of arsphenamin 0.6 gm.; W. R., —, —, —.
9-29-17	Arsenobenzol brand of arsphenamin 0.6 gm.; W. R., cholesterinized antigen, —; syphilitic liver, +; acetone insoluble lipoids, —.
10-2-17	Arsenobenzol brand of arsphenamin 0.6 gm.; W. R., —, —, —.
10-12-17	Arsenobenzol brand of arsphenamin 0.6 gm.; W. R., —, —, —.
10-19-17	Arsenobenzol brand of arsphenamin 0.6 gm.; W. R., —, —, —.
—	Hecht-Gradwohl, weakly +.
11-8-17	Arsenobenzol brand of arsphenamin 0.6 gm.; W. R., cholesterinized antigen, —.
11-15-17	Arsenobenzol brand of arsphenamin 0.6 gm.; W. R., cholesterinized antigen, —.
12-13-17	Arsenobenzol brand of arsphenamin 0.6 gm.; W. R., cholesterinized antigen, +.
—	Nine months Wassermann in Army, negative.
4-4-19	Second attack of syphilis: chancre, roseola, followed by varioliform syphilid.
4-26-19	Arsenobenzol brand of arsphenamin 0.4 gm.; W. R., +, +, +, +, +.
4-29-19	Neo-arsphenamin, 0.75 gm.; W. R., +, +, +, +, +.
5-9-19	Neo-arsphenamin, 0.6 gm.; W. R., +, +, +, +, +.
5-12-19	Arsenobenzol brand of arsphenamin, 0.4 gm.; W. R., +, +, +, +, +.
5-17-19	Neo-arsphenamin, 0.9 gm.; W. R., +, +, +, +, +.
5-20-19	Arsenobenzol brand of arsphenamin, 0.4 gm.; W. R., +, +, +, +, +.
5-26-19	Arsenobenzol brand of arsphenamin, 0.4 gm.

The patient came under my care Sept. 9, 1917. Three days later, the Wassermann reaction with cholesterinized antigen was +, +, +, +; with alcoholic extract of syphilitic liver, +, and with acetone insoluble lipoids +, +, +, +. Between Sept. 22 and Nov. 15, 1917, the patient received eight intravenous injections of the arsenobenzol brand of arsphenamin, the Wassermann reaction becoming negative after the first injection, but relapsing to a weak positive on several subsequent occasions. He was drafted into the Army, and while at two southern camps, because of a deep scar on the glans penis, had a blood test taken monthly for nine months. All of these tests proved negative.

After his discharge from the Army, he again lived with a woman with whom he had been living before he entered the Army. April 4, 1919, he appeared at my clinic at the Polytechnic Hospital with a generalized, pinkish-red roseola. This developed within a fortnight into an extensive varioliform syphilid, covering the face, trunk and extremities (Fig. 1). There was a large chancre on the foreskin opposite the corona (Fig. 2), a site different from that of the first chancre. Six Wassermann tests made between April 26 and May 26 were strongly positive (+, +, +, +) despite seven administrations of arsphenamin and neo-arsphenamin. During this period, the chancre and eruption promptly disappeared under the treatment.

To summarize, the patient contracted syphilis in June, 1917; after treatment with the arsenobenzol brand of arsphenamin he had repeated negative Wassermann reactions until the early part of 1919, when he contracted another chancre, followed by a widespread and severe papulopustular syphilid, and had a strongly positive Wassermann reaction. It is obvious that this patient had been cured.

COMMENT

This case is all the more remarkable in view of the fact that the patient was irregular in his attendance at the University Hospital, and that, through neglect, he developed what were, in all likelihood, evidences of an early meningeal involvement, characterized by headaches, inequality of the pupils, and exaggerated patellar reflexes. It is interesting to observe that not a vestige of immunity against the second attack remained. Indeed, the second attack was more severe than the first, and the Wassermann reaction bids fair to be more resistant to treatment. In this case, the evidence of a second attack is, in my opinion, indisputable. I believe that the deduction that the patient was cured of his first attack is warranted by all of the facts.

Cases of this character are most instructive in the light they throw on the curability of syphilis. The excellent pathologic researches of Warthin at Ann Arbor were persuading many physicians to believe in the dictum enunciated many years ago (under a different therapeutic regimen), "Once a syphilitic, always a syphilitic." I believe that we are in a position at the present day, with more powerful and scientific drugs at our command, to state that syphilis is a curable disease. The criteria of cure are difficult to establish, because the evidential value of negative Wassermann tests is not conclusive. In view, however, of cures such as the one above reported, we may perhaps place more faith in repeatedly negative serologic tests and the absence of symptoms as indications of probable cure.

1922 Spruce Street.

ABSTRACT OF DISCUSSION

DR. JOSEPH ZEISLER, Chicago: Dr. Schamberg brings up the question of innunciations as against the injection of insoluble salts; he presents the subject of reinfection and finally gives us his routine of arsphenamin treatment, a matter in which we are all interested because we would like, at last, to get to something more than experiments. Reinfection of syphilis was observed long before we knew of arsphenamin, and the observation of Dr. Schamberg merely adds another instance to these interesting cases. I do not believe that Dr. Schamberg will be able to convince a majority of his hearers that injections of insoluble salts are not safe as compared to innunciations. That is a subject that has been rehearsed often, and if Dr. Gotheil were here he would be a more able advocate than I. I think every one will go away still adhering to his previous methods. I highly value the innuncination methods, but consider the injection method as excellent and believe the danger of injecting insoluble salts at the present time may be practically ignored. We are much interested to learn of Dr. Schamberg's combined treatment. It is a fine point, this injection on alternate days and the innunciations on off days. I have personally for sometime, at least in fresh cases, practiced the intensive arsphenamin treatment on three successive days, as advocated by Dr. Pollitzer, following it with innunciations, or injections; but these are merely technical details.

DR. WILLIAM H. GUY, Pittsburgh: We all understand that in the treatment of syphilis we are dealing with a chronic infection by *Spirochaeta pallida*, and that a cure depends on our ability to destroy every spirochete with which the individual is infected. We also know that we have two drugs, arsphenamin and mercury, which are effective spiro-

chetics, arsphenamin being the better of the two. As Dr Schamberg has pointed out, the result he is able to obtain is dependent not only on the frequency of dosage but on the size of the dose, the aim being to secure as high a concentration of the drug in the blood stream as possible in order

mercury and arsphenamin at the same time and to give as much as is consistent with safety. We all realize the objections that can be raised against the intramuscular injections of the insoluble salts of mercury and against inunctions. I hope that Dr. Schamberg will at some future time make some studies of the soluble salts of mercury used intravenously. Some of the French physicians have for a long time used the cyanid, but I know of no studies as to its relative effect on the Wassermann reaction. I have frequently used it with no injury to the veins and no other untoward results, though it is said to cause duodenitis occasionally and rarely hemorrhagic duodenitis in susceptible patients. A thorough study of the effect of this method of treatment would be of interest.

DR. HARRY G. IRVINE, Minneapolis: The principal object of attempting to treat people for syphilis is to arrive at a cure of their syphilis. It seems a lamentable thing that during the past eight or nine years during which we have had arsphenamin, most of the time has been spent in attempting to arrive at some standard method for giving arsphenamin, and each year has brought forth some new combination of arsphenamin and mercury, whether it should be given with, or after, or before, or what not, and a great many papers have been written to show that such and such a treatment in such and such a time brings forth a negative Wassermann. I think we have devoted altogether too much effort to this sort of thing and not a sufficient amount of effort to following cases treated with a certain technic, a number of years ago, and bringing out to the profession what has really been accomplished in the "long distance" cure of these cases. I do not believe that anybody is prepared to say yet that a negative Wassermann extending over a year or year and one half means a cure of syphilis. We may find that patients who remain serologically well for a period of years may still bring forth paresis and tales but sufficient time has elapsed so that some figures could be forthcoming if the men would devote their time to taking up these old cases and showing the results of treatment from every standpoint, rather than producing a negative Wassermann.

DR. HENRY H. HAZEN, Washington, D. C.: For the past two years I have been using arsphenamin in much the same way as Dr. Schamberg has reported and now have seventy-five cases. In two cases when the interval was reduced to two days, a very severe urticaria developed after each injection. We then proceeded with the injections by the method Stokes brought out—the use of atropin preceding injections. At three days intervals the results were very good but in two cases very bad urticaria developed in the two days' interval.

DR. JAY FRANK SCHAMBERG, Philadelphia: I trust that Dr. Zeisler has not misunderstood me in what I stated concerning the use of insoluble preparations of mercury. In using arsphenamin it is important that the drug should be eliminated properly through the kidneys. Whenever an injection is given, a certain amount of the drug is deposited in the liver and in certain

to destroy as many spirochetes as possible in the short length of time arsphenamin remains in the blood stream. I would like to ask Dr. Schamberg if he does not think that results would be better if larger doses were given. We know that Ehrlich failed in his attempted "therapia magna sterilisans" because of the rapid elimination of the drug. It has been shown by Swift and Ellis that there is but little spirochetal action on the part of the blood serum six hours after administration of a full therapeutic dose of arsphenamin. Inasmuch as the destruction is immediate and depends on the concentration in the blood stream, I think that the best results would be obtained by using as great an amount in the blood stream as could be tolerated. I have used the plan of Dr. Pollitzer in which arsphenamin is given on each of three successive days at the rate of 1 gm. to each 30 pounds of body weight in a series of fifty cases without any bad results. Keizer of Indiana prefers neo-arsphenamin on account of lower toxicity and aims to obtain a sustained saturation of the blood stream by the drug. He gives a 9 dg. dose at one hour intervals. It is new and has not been tried extensively, but is worthy of consideration. He claims better results than by anything else. Regarding mercurials, every one is familiar with the objections to inunctions. The fact that we are able to give patients a large amount of mercury intramuscularly and keep them saturated with the drug without bad results is too definite to be disproven. In my series of 30,000 intramuscular injections I have made a note of but a single serious reaction. In the large number given in the army it has been infrequent that any trouble has developed, and if the patient is carefully examined before the injection, regarding particularly the condition of his elimination apparatus, and then following his injection his reactive phenomena are noted and dosage estimated accordingly, the injection method may be pursued, I believe to better advantage than the inunction.

DR. JOHN E. LYNN, New Haven, Conn.: I think we all agree with Dr. Schamberg that the proper method of treating syphilis, and especially early syphilis, is to give the patient

mercury and arsphenamin at the same time and to give as much as is consistent with safety. We all realize the objections that can be raised against the intramuscular injections of the insoluble salts of mercury and against inunctions. I hope that Dr. Schamberg will at some future time make some studies of the soluble salts of mercury used intravenously. Some of the French physicians have for a long time used the cyanid, but I know of no studies as to its relative effect on the Wassermann reaction. I have frequently used it with no injury to the veins and no other untoward results, though it is said to cause duodenitis occasionally and rarely hemorrhagic duodenitis in susceptible patients. A thorough study of the effect of this method of treatment would be of interest.

Fig. 1.—Varioliform syphilis: eruption of second attack.

Fig. 2.—Eruption on thigh: scar of old chancres on glans; second chancre on foreskin over corona.

injections of mercury are given, there is an accumulation of the drug from week to week. Dr. Zeisler is correct in stating that cases of second attacks of syphilis have been reported in the literature. I am not familiar with any cases in which such a long chronologic record has been available of the Wassermann test during the first attack, the interim, and a second attack. We realize that there is nothing new in the method of treatment which we have suggested. Physicians are groping for a technic which will secure the best results. Each syphilologist today treats syphilis according to his own experience; one man uses an extremely intensive treatment with successive daily injections in full dosage; another uses weekly injections, still a third combines mercury and arsphenamin, etc. We submit the method which we have described for what it is worth and for the trial of others. It will of course be necessary for us to study serologically the cases in which negative Wassermans have been induced, for as long a period as it is possible to keep them under observation. The advantage of the method in question is that we use the two important remedies in syphilis, but use each in smaller dose than when it is used separately, and at the same time we increase the frequency of the intravenous treatment. By shooting with two arrows, we are more apt to kill the spirochete than by aiming with merely one. We have found it possible to give three weekly injections of arsphenamin in 0.3 gm. doses, with injections on alternate days, for several weeks, without materially disturbing the patient's well being or producing any damage to his organs. With respect to the use of soluble preparations of mercury intravenously, we have had quite a little experience. Even when the mercurial salts are used in 50 c.c. of water it has been our experience that the veins became so sclerosed that it renders them unfit for subsequent arsphenamin injections. We have used bichlorid, succinimid, the cyanid and other salts, but with the same effect. Syphilis is probably the greatest medical problem that the world has to deal with at the present time. We are persuaded that it is a curable disease, and that is an important consideration both for patients and for physicians. The matter to be determined is the best and safest method of bringing about this cure.

STRICTURE OF THE RECTUM*

FRANK C. YEOMANS, M.D.

NEW YORK

Stricture of the rectum, excluding neoplastic stenosis, is not a disease entity but is the result of a congenital malformation, or of an infection, inflammation, irritation or trauma (either mechanical or surgical). In form, strictures are annular, tubular or valvular.

ETIOLOGY

Broadly speaking, all strictures are congenital, traumatic or inflammatory.

Congenital Strictures.—These occur at the junction of the anus and rectum, and are due to imperfect or incomplete absorption of the anal membrane. As a rule, they are recognized early, and then methodical dilatation usually effects a cure. A partial membrane may persist, requiring surgical removal, or ulceration may occur above it, causing a true fibrous stricture.

Assigned Causes of Traumatic Stricture.—These are pressure of the fetal head in prolonged labor, foreign bodies (enteroliths), unskilled instrumentation and operations for hemorrhoids, fistula and resection.

I have seen no instances in which pressure of the fetal head has caused a stricture, though I have operated successfully in four cases of rectovaginal fistula following prolonged labor; but no stricture was pres-

ent. Foreign bodies perforate the mucosa, causing abscess, and enteroliths may be the cause of extensive ulceration; but stricture has not followed in the cases I have seen, though, of course, it is possible. In one of my cases, stricture was due to clumsy instrumentation.

Stricture should never follow a properly performed hemorrhoidectomy. In the ligature or clamp and cautery operations, the tumors are removed in the axis of the bowel, leaving a strip of mucosa between the adjacent hemorrhoids. To insure a canal of normal caliber and to hasten the absorption of exudate, digital dilatation is begun on the fifth day and repeated twice weekly for a month till healing is complete.

Stricture may follow a Whitehead operation, especially if union is not primary. Other equally unfortunate sequelae caused me to abandon the Whitehead operation many years ago, and I believe that can have no place in the surgery of a condition that can

Fig. 1.—Rectum almost obliterated by syphilitic stricture.

always be cured by a safer and simpler operation. Incontinence rather than stricture is to be feared after operation for fistula. Certain neglected cases of blind external and blind internal fistula may, however, form stenoses. In the latter, the only opening is between the anal sphincters. Tonicity of the sphincters impedes drainage and infiltration, and connective tissue formations extend circularly around the intestine, forming a stricture at the level of the internal sphincter, as occurred in two of the cases reported. Resection of the rectum and end-to-end suture are usually followed by some degree of stenosis at the line of union. This is a valid argument against resection and in favor of perineal extirpation whenever anatomically possible.

Inflammatory Strictures.—These comprise by far the largest group, and they are of the greatest clinical importance. The infection may be simple or specific. So-called simple infections include amebic and bacillary dysentery; gonorrhea, and infection by colon bacilli, streptococci and staphylococci, of various strains, leading to acute and chronic inflammation. So,

* Read before the Section on Gastro-Enterology and Proctology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

far from being simple, these infections are still quite obscure and complex. The possibility of a simple infection causing a stricture is debatable. Unless the submucosa is extensively involved, clinically a stricture seldom, if ever, occurs. In four cases of bacillary dysentery, more than 100 cases of amebic dysentery, six cases of gonorrhea of the rectum, and a large number of cases of chronic ulcerations of mixed types of infection, many of the latter involving the entire colon and rectum and personally observed for several years, no patient has developed stricture. These limited observations accord with the more complete statistics of Woodward,¹ who states that no cases of stricture following dysenteric ulceration were reported during the war, or have been since. Among the United States troops there were 287,522 cases of dysentery, 28,451 being of the chronic form. Deaths numbered 9,431, of which 3,855 occurred in chronic cases.

Specific Infections.—The specific infections are tuberculosis and syphilis.

Tuberculosis: It is generally conceded that tuberculosis of the intestine in adults is clinically always secondary to a pulmonary lesion, either active or quiescent. Tuberculosis tends to cause stricture of the small intestine and cecum rather than of the terminal colon. The comparatively frequent occurrence of intestinal tuberculosis without stricture formation is noteworthy. Just why this should be so is not clear, but seems to depend on two factors: (a) the way the tissues react to the tuberculous infection, and (b) the character and amount of secondary infection present. If the natural resistance of the host is weak, secondary infection predominates, and the inflammation is likely to be destructive. On the contrary, if the host possesses strong natural resistance, productive inflammation may occur, with the formation of cicatricial tissue and a stenosis.

Syphilis: This, in the tertiary stage, is rightly agreed to be the commonest infection causing stricture. It was the cause of 80 per cent. in my series of inflammatory and perirectal cases.

Gummas and obliterating endarteritis and, according to Kieder, a proliferation of the intima of the rectal veins even to their obliteration, are responsible for the ulcer. If the ulcer is not healed, there is a rapid production of connective tissue, and the foundation of a stricture is laid. The reason syphilitic strictures occur more often in women than in men (sixteen females as compared to eight males in my cases) is explained by Quinn and Hartmann on anatomic grounds. The lower group of rectal veins anas-

tomose directly with branches of the external pudendal, and the latter originate in the posterior commissure of the vulva, the chief seat of syphilitic infection.

PATHOLOGY

Whatever the nature of the infection, the steps in the formation of inflammatory stricture seem to be much the same, namely:

1. Infection and inflammatory process.
2. Ulceration of the mucosa.
3. Round cell infiltration and production of connective tissue, which tends to encircle the bowel.
4. Persistent contraction of this new-formed fibrous tissue.
5. Compression and atrophy of the muscle.

In a word, the formation of inflammatory stricture depends on an extensive production of connective tissue which persistently contracts.

The pathology explains the marked tendency to ulceration below syphilitic stricture. By inflammation

and compression of the vessels, the arterial blood supply is limited, while the return flow is obstructed; so the natural tendency of the ulcers to heal is weakened, and their response to local and constitutional measures is impaired.

OTHER STRICTURES

Spasmodic or Phantom Strictures.—Most authorities deny the occurrence of spasmodic or phantom strictures, while a few others have reported isolated instances. They are alleged to occur at the site of attachment of the levator muscles to the rectum and at the rectosigmoidal juncture. Failure to pass the sigmoidoscope into the sigmoid is, in my experience, the consequence of (a) an anatomic condition, the acuteness of the angle at the rectosigmoidal juncture; (b) a pathologic condition, as represented by constricting peritoneal bands and adhesions, and (c) is rarely attributable to spasm, the spasm being temporary. No case of cicatricial stricture that I have seen was due to muscular spasm.

Valvular Stricture.—This is a special form of the inflammatory class. The valves of Houston, non-obstructive, resilient structures normally present in the rectum, are a frequent site of inflammation and ulceration, with consequent infiltration and contraction, and thus occasionally they become the site of a stricture.

Perirectal Strictures.—These may be due to inflammation in adjacent organs, or they may follow an operation on them.

DIAGNOSIS

A history of progressive constipation and futile straining at stool, or frequent fetid passages, suggests a local examination, by which a stenosis is easily recognized. It is necessary, however, not only to discover

Fig. 2.—Bougie inserted through rectal stricture. Second stricture in transverse colon. Confirmed by operation.

¹ Woodward, J. J.: Medical and Surgical History of the War of the Rebellion.

the stricture but also to determine its nature, size, form and length, and the degree of infiltration and extent of ulceration above and below it. Most strictures are within the palpable area—the lower 4 inches of the rectum—forty-seven of my fifty cases being within 10 cm.

Congenital and traumatic (including operative) strictures present few difficulties in diagnosis. They are usually annular, and ulceration is limited or absent. Inflammatory strictures, however, must be differentiated from carcinoma. Carcinoma usually begins abruptly and has a sulcus below it. The growth itself is ulcerated and characteristically feels irregular, hard and nodular. The approach to an inflammatory stenosis is generally a gradual, cone-like, firm contraction. The mucosa below, when ulcerated, feels granular.

After the digital examination, I employ the graduated proctoscope of my model, one-half inch in diameter and 10 inches long. Through this, the examiner can note the ulceration below, discover strictures beyond the reach of the finger, pass the tube through the lumen in nearly all cases, and so determine their length and see the extent of any ulceration above. By using a tube of larger caliber, a specimen forceps, which I have devised for the purpose, can be introduced and the tissue secured for histologic examination when malignancy or tuberculosis is suspected. Scrapings may also be taken from the ulcerated surface for examination for tubercle bacilli.

Finally, roentgenograms are made twenty-four hours after a bismuth meal and also after a barium clyisma. These (a) outline the stricture (Fig. 1); (b) demonstrate others at a higher level, a rare occurrence but one to be anticipated (Fig. 2), and (c) show the length of sigmoid available in case of operation.

A Wassermann test of the blood should be taken in every case of stricture. The reaction is positive in most cases of syphilitic stricture, and in my series occurred in 86 per cent. of the cases. The tuberculin reaction is so often positive in adults that little reliance can be placed on it for diagnosis.

PROGNOSIS

The prognosis varies with the nature of the stricture and the treatment instituted. For congenital and traumatic cases the prognosis is good. For inflammatory strictures, the tuberculous excepted, good management will insure a life of comparative comfort in most cases, and sometimes an operative cure can be effected. If neglected, abscess, fistulas, obstruction and toxemia lead to a fatal issue.

TREATMENT

Preventive Treatment.—Nearly all operative strictures could be prevented by proper surgical technique and suitable postoperative care, as indicated under "Etiology." It was noted under "Pathology" that an ulcer is the usual initial gross lesion in inflammatory stricture. Most ulcers in their early stages respond to local and constitutional treatment, healing with a scar limited to the mucosa or mucosa and submucosa, with no marked narrowing of the bowel lumen. Thus, the greatest measure of prevention is to heal the ulcer in the prestricture stage.

Treatment After Development.—When a stricture has developed, the treatment is constitutional, local and surgical. Patients in the majority of advanced cases are debilitated and underweight. The diet should be liberal, excluding only fermentable foods. In syphilitic cases arsenphenamin should be administered till the Wassermann reaction is negative, if this can be accomplished without inducing arsenical poisoning, and should be followed by mercury given hypodermically, and the iodids. Specific treatment does not affect the cicatricial tissue already formed, but is employed as a general measure.

Dilatation has a very important place in the management. Patients in some cases can by this means be carried along very comfortably without operation, and dilatation is always employed after proctotomy to maintain the patency. Forceful dilatation by metal instruments or hydrostatic pressure is so likely to rupture the bowel that it should never be used. The safest instruments for dilatation are soft rubber Wales bougies in graduated sizes. Beginning with the largest that can be introduced comfortably, bougies are passed semiweekly in increasing sizes until a No. 7, at least, can be retained for from ten to fifteen minutes. The bowel is irrigated daily with a 2 per cent. peroxid solution.

While dilatation seldom cures a cicatricial stricture, it will enable many of its victims to lead a life of comfort and health, handicapped only by the little extra time required for the treatment.

Surgical Treatment.—This includes proctotomy, colostomy and excision.

Proctotomy is the incision of the rectum. If the incision is made above the sphincters, it is termed internal proctotomy; if through the sphincters, external proctotomy. Internal proctotomy is occasionally employed for valvular strictures, but it is preferable to divide them with a spring clip devised for the purpose. Filtrous strictures are usually near the anal strait and are accompanied by extensive ulceration

Fig. 3.—Stricture of rectum removed by perineal extrusion, 1909. Patient cured.

and supuration, requiring the free drainage that external proctotomy affords. Beginning in the mucosa, 1 or 2 cm. above the stricture, the stricture, both sphincters and all intervening tissues are divided by a clean incision carried back to the tip of the coccyx. Hemorrhage is controlled by superimposed strips of gauze, and a half-inch rubber tube is passed up beyond the incision. The bowels are confined from five to eight days, and thereafter irrigated daily and bougies passed to prevent recurrence. While proctotomy does not cure an inflammatory stricture, it is a perfectly safe procedure that any surgeon can execute quickly, gives immediate relief, and is one of the most beneficial operations.

Colostomy for stricture is for either a temporary or a permanent purpose, and is made in the sigmoid or the transverse colon. If a colostomy is performed preliminary to excision, it is temporary; but if radical treatment is not contemplated, a permanent artificial anus is formed. Colostomy enables us to explore the abdominal cavity, relieve obstruction and toxemia,

REPORT OF CASE

In illustration is the case of Mrs. M. B., aged 31, who complained of constipation and rectal discharge for ten years before I saw her in 1909. Forcible dilatation under ether had been performed seven and four years before, and bougies passed at irregular intervals. A syphilitic stricture began just above the anal strait, admitting only a 13 F. urethral catheter. Vaginal examination indicated that the stricture was about 2 inches long. Aug. 24, 1909, I performed a perineal extirpation, removing 5 inches of the rectum (Fig. 3). The patient is now well, weighs 128 pounds, as against 104 when operated on, and has one or two formed stools daily, with perfect control.

SALIENT FEATURES

The salient features of the accompanying table are:

1. Thirty-seven of the fifty cases, including the seven in which strictures were due to fistulas, were inflammatory.
2. Twenty-four, or nearly 50 per cent. of all cases, were syphilitic.
3. Of the patients in the syphilitic cases, eight were males and sixteen females; sixteen were white and

FIFTY CASES OF STRICTURE OF THE RECTUM

Classification	No. of Cases	Average Age	Sex		Race		Wassermann			Location		Form			Treatment				Result

and prevents constant infection and irritation of the strictured area.

Indications for colostomy in the transverse colon are: (a) a short sigmoid, when it is proposed to perform a perineal excision later, and (b) demonstration by roentgenograms of another stricture at a higher level, as occurred in one of my cases (Fig. 2).

Excision, theoretically at least, is the ideal treatment for organic stricture. With our increasing experience and success in the perineal and the abdominal operations for extirpation of the rectum for carcinoma, we should endeavor to apply similar methods to suitable cases of stricture. When feasible, excision should be performed either as a primary operation or secondary to colostomy, after active infection has subsided, complicating abscesses and fistulas have healed and the patient's general condition has improved. With a sigmoid of average length (16 inches), from 6 to 8 inches of bowel can be removed by the perineal operation without great difficulty in most cases, and this would cover all rectal strictures. The modified technic of Quenu and Hartmann is to be preferred.

eight colored; the Wassermann reaction was positive in eighteen and negative in three clinically syphilitic, and in three cases the test was not made. The reaction was therefore positive in 86 per cent. of the cases in which the test was made.

4. In forty-seven cases, or in 94 per cent. the strictures were within 10 cm. of the anus, and therefore palpable.

5. The patients in forty cases were treated and observed for a long time. Of these, one, tuberculous, died in three years; the condition in twenty-nine was improved, that is, the patients have maintained comfortable lives, and ten, two of them syphilitic, were cured.

171 West Seventy-First Street.

ABSTRACT OF DISCUSSION

DR. JOHN L. JELKS, Memphis, Tenn.: Gonorrhea is a prevalent cause of stricture of the rectum, especially among the colored race; but gonorrheal strictures are usually lower and begin in the anal canal almost always. Tuberculosis and chancreoid with ulceration are also prominent causes of

stricture. Syphilis is more often a cause of stricture than is admitted or than is proved. Many strictures of the rectum that are known to be syphilitic give a negative Wassermann. I am glad to note, however, that the doctor is having his Wassermans' made from the spinal fluid. These strictures that are syphilitic in origin primarily are not syphilitic in the end. They are mixed infection, ulcerations and fibrous infiltration. Some of them are very hard and do not constitute a syphilitic mass. Dysentery is often but not quite so often as some other diseases a cause of stricture. I have seen a number of dysentery ulcerated strictures. I am not sure, however, that there was not a secondary or associated infection. Cancer, when it appears to produce stricture, is more often higher. That is a diagnostic point well worth consideration. I have been amazed at the lack of symptoms in some cases. I have performed at least two colostomies in the last year, one of them on a negress brought into the operating room to be operated on for hemorrhoids, no diagnosis of stricture having been made. There was almost a complete obstruction and the intestine and stomach were enormously dilated, the woman in such deperate condition that it was necessary to immediately perform a colostomy. A few weeks ago another negress had a diagnosis of appendicitis made until by accident one of the physicians tried to put his finger into the rectum. Colostomy was absolutely necessary as a means of saving her life. In the treatment mercury and iodids should be avoided unless the mercury is given in the tissues, and not by the mouth. Avoid iodids. I believe they are contraindicated and should not be given. Arphenamin in its various forms is our best means of immediate syphilitic treatment, but is worthless when late strictures have developed. Surgical drainage is the first drainage. If it is a late stricture, however, fibrous structure having been thrown out, there is absolutely no cure for those cases but enucleation of the rectum, and that should always be considered as early as is at all safe for the patient's welfare; because when external or internal proctectomy is performed, whatever one may do to drain the patient must be told: "You will not be well. Therefore, you must consider the fact that in the end you must have this rectum removed."

Dr. HOLLAND H. DONALDSON, Pittsburgh: The percentage of cases of stricture of the rectum depends on several things. First, it depends on the part of the country from which the patients come. The percentage given by Dr. Yeomans would be the average percentage of nonmalignant strictures as treated in our northern cities. This is rather an unusual report of fifty nonmalignant strictures. It is a great relief to hear of some major surgery of the rectum for nonmalignant disease, because we find such a large percentage of incurable or inoperable strictures of the rectum due to cancer. The only class of strictures of the rectum the surgeon can prevent is the class of cases due to traumatism by operation. I would agree with Dr. Yeomans that the Whitehead operation as a routine operation for hemorrhoids should be discontinued, but I hardly agree with him that it should be discontinued entirely. I believe that in cases of hemorrhoids, associated with prolapse of the mucous membrane, where the other operations which deal with individual hemorrhoids are not specially applicable, it is the operation of choice. But it is not an operation for the novice. It is an operation for good surgical technic, especially with reference to prevention of traumatism of tissue, injury to the sphincter muscles and prevention of tension of sutures which is the most important of all. The tissues should be cut as you suture them. Light catgut sutures should be used and interrupted sutures rather than continued sutures. I believe a Whitehead operation in such a case, performed by good surgical technic, is the operation of choice. I would like to ask Dr. Yeomans to tell us how he performs the operation of colostomy and if he has had intussusception occur through an ordinary colostomy opening. I have had this complication occur during the last year in a patient on whom a simple colostomy was done for a hopeless cancer in which there was already metastasis in the liver. In that case the colostomy was done by making a McBurney incision, drawing

the bowel up and holding it by a glass rod. In three months that patient developed an intussusception.

Dr. J. RAWSON PENNINGTON, Chicago: The etiology of rectal stricture is still in doubt. Syphilis as a causative factor has run the gamut of professional opinion, vehemently advocated and just as vigorously denied. As in tuberculosis, stricture may occur in syphilitic individuals as a coincident. In the fibrous type the transformation involves all the intestinal tunics alike; consequently, the mucosa is adherent and cannot be separated. At the upper end of the stricture, however, this fibrous transformation may cease abruptly and the mucosa remain normal. In June, 1916, after a cursory clinical examination, I did a posterior proctectomy on a close fibrous stricture 2½ inches in length and probably tuberculous, in a patient 35 years old. After the incision the mucosa was loosened for about ½ inch around the upper angle of the wound. A "U" suture of heavy braided silk was passed through the proximal angle and out through the distal angle and tied, thus approximating the upper and lower angles. Similar sutures were passed through the loosened mucosa and made fast to the mucosa and skin at the lower angle of the wound. Eighteen months later the patient returned, saying the stricture had recurred. Only a thin veil of mucous membrane at the anorectal junction was found. This was easily broken and a No. 9 Wale's bougie passed readily through the entire strictured area. The roentgen ray revealed tubercular deposits in lungs at this time. In my experience medication is futile in organized rectal strictures. Recently, however, I have observed that modern methods of treatment may control and check syphilitic hemorrhagic proctitis and ulcer, which might lead to stricture. Rectal stricture—one of the great banes of syphilis—can be prevented if ulcer is treated early before great destruction begins. This leads me to again urge periodic proctoscopic examinations. Some years ago I succeeded in dilating a colostomy stricture from the size of a small probe to that of one's thumb by keeping it packed with small pledgets of cotton covered with petrolatum. This success induced me to use one of my rectal tampon covers in a similar way in rectal stricture with some degree of success.

Dr. J. COLES BRICK, Philadelphia: Dr. Yeomans has presented an instrument for the purpose of diagnosis. The pathologists of the Jefferson Hospital tell me that a crushed section removed by any cutting instrument is not suitable for the purpose of diagnosis and ask for a nice, cubical piece. If the stricture is where the peritoneal vessel occurs that is particularly dangerous. If you do not get a correct diagnosis you are misled. If you attempt to remove or do remove a proper section it is dangerous. Therefore, I say that the diagnosis is properly made by clinical judgment and secondary symptoms. Do not take out a crushed section; you will be misled. Do not try to remove a proper section or you will do damage.

Dr. DWIGHT H. MURRAY, Syracuse, N. Y.: In securing a section, I use a snare, and I find that I can cut tissue in that way without any crushing. I do not remove it rapidly. I put the snare over the tissue that I want to take, and then take about ten minutes in drawing the snare up so as to cut the section off. Then I do not get the excessive bleeding that might follow rapid removal of the section. A child 10 months old was brought to me six months ago. The child had a congenital stricture and had been passed around from one physician to another until three or four had seen the case. The child had never had a proper bowel movement and could not have had with the stricture it had. Last September when the child was a year old it began to make peculiar straining and pressure, and crying with every stool. When I saw the child it had a mass as large as a baby's head and I could just about get the tip of my finger into the anal canal. The only bowel movement that child was getting, notwithstanding that it was getting castor oil and cathartics and enemas, was just a little washed out from the outside. I did a posterior proctectomy, and then proceeding with my mining tools to dig out the "pay dirt," I got a full pint can of hard feces, dry and hard as timber, so that it would sound like a stone when it dropped into the pus basin.

Then for five days after that every morning I would get a few more of the same degree of hardness, showing that the colon was filled from one end to the other with this impaction.

Dr. E. G. MARTIN, Detroit: I wish to emphasize the non-surgical treatment of syphilitic stricture. In seven cases from our clinic at Harper Hospital, which were tentatively diagnosed as syphilitic from the history and examination, and afterward verified by the Wassermann blood test—all occurred in colored people. Most of these strictures were small in caliber but dilatable by the finger without anesthesia; one patient required anesthesia, being very sensitive. However, the stricture was easily dilated and cleared out without instrumentation. Three are symptomatically cured, all have greatly benefited from antisyphilitic treatment, and dilatation once or twice a week. I have referred particularly to the annular strictures, the tubular cicatricial ones usually requiring more radical treatment. Of the seven blood Wassermans, one was negative; of three spinal fluid Wassermans, but one was positive.

Dr. JOHN L. JELKS, Memphis, Tenn.: Will some physician tell us in what proportion of cases he gets a positive Wassermann from the blood and what proportion from the spinal fluid?

Dr. CHARLES DRECK, Chicago: In the cases of old syphilis or patients who may be suspected of having syphilis, when they have drifted around to several practitioners, it is unreliable to try to get Wassermans of the blood, and I have limited all my examinations where I really am anxious about them to spinal punctures, and I place a great deal more dependence on this, believing that when I get a negative it is a negative.

In those cases where we have a differentiation come up between a benign and a malignant tumor I feel that the loss of weight is sometimes important. In all these rectal cases there is disturbed digestion, not necessarily a disturbed assimilation; but if that disturbed digestion has gone on for a reasonable length of time, two or three years, and the patient has not lost weight, we can infer that it is not progressive. On the other hand, a case that has gone on with disturbed digestion, with pelvic symptoms suspicious of cancer for a couple years, I feel must lose some weight. I do not see how they can keep up their weight in the malignant cases.

Model Dairies in Mesopotamia.—According to U. S. Consul Oscar S. Heizer, at Bagdad, the British military authorities have established model dairy farms at Bassorah, Amara, Kut, Bagdad, Ramadi, Hillah and Nasiriyah. These are managed by experts and the milk is treated under hygienic conditions. Each farm has been equipped with an up-to-date dairy plant and machinery and the whole dairy produce, consisting of milk, cream, and butter is turned over to the military hospitals. Large numbers of cattle have been imported from India and efforts are being made to improve and increase the herds in Mesopotamia. *Commerce Reports.*

Clinical Notes, Suggestions, and New Instruments

THE WHISTLE TEST: AN AID IN THE DIAGNOSIS OF GASTRIC TUMOR

ROBERT M. LEWIS, M.D., BALTIMORE

In the field of abdominal surgery, nothing is more important and interesting than making the diagnosis in a case of puzzling abdominal tumor. Often one cannot tell at all at first sight just what organ is involved. Arriving at the right anatomic diagnosis often depends on the careful elimination of several possible contiguous sites of disease.

In the upper abdomen, a variety of tumors are frequently encountered. In this region, where the stomach is the commonest organ primarily involved in the event of a new

growth, a cancer of the pylorus or greater curvature has frequently been mistaken not only for malignant disease of other organs, but also for a movable kidney or spleen, a cyst of the pancreas, a retroperitoneal growth, an enlarged gall-bladder, or an intraperitoneal abscess.

A skilled examination by use of the roentgen ray usually determines, fortunately, whether or not the stomach is at fault. The stomach tube also often gives circumstantial evidence of the presence of gastric cancer in the form of blood; but in the absence of this finding one cannot exclude malignancy.

Blowing up the stomach by Seidlitz powders or other means is a rather dangerous and unreliable way of outlining the organ. For several years I have employed a simple means of quickly and accurately determining the boundaries of the stomach, and in a number of puzzling cases have plainly proved or disproved the gastric involvement before the patient came to the roentgen-ray room or operating table. The method is so easy and efficacious that possibly it is in use

Palpable intraperitoneal masses: A, gastric growth; B, tumor not springing from stomach.

elsewhere; but I have never seen it employed in any other clinic and therefore venture to describe it.

The patient with an intra-abdominal tumor of an unknown point of origin is fed a fine duodenal tube equipped with any one of the usual types of metal buckets. This is swallowed with two glasses of water. If there is any difficulty with choking, it can often be overcome successfully by enclosing the metal piece in a gelatin capsule. A rubber syringe or injection bulb is connected with the free end of the duodenal tube. When the stethoscope is placed over the epigastrium and little spurts of air are suddenly injected through the tube into the stomach by squeezing the bulb, the listener at once hears a bubbling or whistling sound under the stethoscope, apparently right in his ear. In moving the stethoscope bell about he continues to hear, as long as it is placed directly over the stomach, a sharp direct sound. As soon as the stomach border is passed, however, and the bell is placed over the celiac or small intestine, the sound at once becomes distant

and less distinct. In this way the organ can be mapped out with remarkable exactitude.

Next, let the bell be placed over the tumor. Here, if the mass is a gastric growth, the sound will continue to be heard close at hand, as over the stomach. On the other hand, if the mass springs from a neighboring organ, no matter how near it lies, the sound produced when the air is injected at once seems quite distant. So great is the difference in the transmission of the sound that no experience of previous trials is necessary for the examiner to say immediately and with certainty that the mass in question is or is not a gastric tumor.

The test is easily applied and, without upsetting the patient, gives valuable information. It would seem worth while to determine the position and outline of the stomach in this way every time a tube is passed on a new patient. I have examined a number in cases in which the diagnosis was in doubt, and the method has so far never failed me.

A glance at the illustration will be found helpful. *A* and *B* indicate palpable intra-peritoneal masses: *A*, a gastric growth; *B*, a tumor not springing from the stomach. Listening over the stomach or over *A* will give the same nearly distinct sound, while over *B*, though near the stomach, the sound is distant.

It is likely, too, that the same test will prove of value in examining growths in the left iliac fossa. By introducing the bucket into the sigmoid or rectum it is reasonable to suppose that the sound will be transmitted along the ascending colon. In this way tumors of the ascending colon can probably be distinguished from retroperitoneal and other growths.

STEREOSCOPIC ROENTGENOGRAPHY WITH FILMS

HOWARD CURLE, A.B., M.D., MADISON, WIS.

One objection to the use of films in roentgenography has been the difficulty of holding the films in the viewing box. This may be done by placing the films between two clean glass plates and securing them with spring clips or adhesive tape. If but few cases are handled each week, this method will do very well, but becomes rather irksome if many cases are handled daily.

To meet this objection we have had made, for our use, a film holder which is shown in the accompanying sketch. The

Film holder for holding films in the viewing box in roentgenography: (a) frame; (b) brass spring; (c) clip; (d) spring and clip in place.

frame (a) is made of galvanized iron. It should be heavy enough not to bend easily. The outside dimensions are the same as those of the film with which the holder is to be used. Each side and end are from one-half to three-fourths inch wide, depending on the size of the frame and the weight of the material. Across each end is a brass spring (b). One end of the spring should bend around the edge of the frame and be riveted on the under side, so that the spring is free from the form on the upper side and will admit the film to the edge of the frame. The other end of the spring is brought down and held with a brass clip (c).

These film holders can easily be made by any tinsmith or plumber, and if a number are kept on hand, films may quickly be inserted for the viewing box.

With this arrangement, stereoscopic work may be done just as satisfactorily and easily as with plates, and especially is this true if the double coated or duplited films are used, as they are stiffer and more easily handled than the single coated film.

DURAL SEPARATOR AND BONE ELEVATOR FOR CRANIOTOMY

AUGUST M. HANSON, M.D., FAIRBULT, MINN.

This illustration, actual size, represents an instrument for separation of the dura from the internal table and elevator for fragments of the internal table following the use of the drill in craniotomy preparatory to the cutting of the osteoplastic flap. The instrument is inserted to the dura,

Dural separator and bone elevator for craniotomy.

portions of the remaining internal table are lifted up, and the instrument is rotated between the thumb and forefinger, separating the dura from the internal table well beyond the margins of the opening made by the drill.

RESECTION OF THIRTEEN FEET OF ILEUM

JOHN R. LITTLEFIELD, M.D., CUMBERLAND, MD.

S. W., a woman, aged 22, married, nullipara, weight, 110 pounds, admitted to the Western Maryland Hospital, March 23, 1919, had been operated on for pus tubes in September, 1917, drainage being required. This operation was followed by an uneventful recovery and good health until March 15, 1919, at which time she consulted her physician for the relief of abdominal pain associated with vomiting and preceded by constipation. Her condition increased in severity and, March 22, the vomitus assumed a fecal character. Small semisolid bowel evacuations occurred, March 17 and 18. On the night of March 22, she was placed on a train and brought to the hospital, a distance of 150 miles.

On admission the vomitus was of a distinct fecal character; the temperature was 97 by mouth; pulse, 120, and respiration, 20. The abdomen was greatly distended, and was very tender and rigid. Peristalsis was absent. There was no hernia in the scar of the previous operation. The old scar was excised and the peritoneal cavity opened, a moderate amount of blood-stained fluid escaping with the protrusion of a large segment of gangrenous and distended bowel. Large areas of peritoneum had sloughed from the bowel wall, and the muscular coat was plainly visible in these areas. The omentum was found to be rolled into a firm band and, with a knuckle of intestine, was firmly adherent to the left horn of the uterus. These adhesions were broken and the entire loop of gangrenous bowel was delivered from the abdomen. This loop, including sound tissue at each end, and measuring 13 feet, was isolated by ligating with small tape and then excised, the mesentery being rapidly transfixed and ligated as the resection progressed. An end-to-side anastomosis was made by sutures, an end-to-end anastomosis being impossible owing to the tension which would have resulted, there remaining only 6 inches of the jejunum and what appeared to be about 4 feet of the ileum. The abdomen was closed without drainage. One hour and ten minutes was required for the operation.

The after-treatment consisted of maintaining the Fowler position, rectal drip tap water for the first twenty-four hours, followed by a 10 per cent. solution of glucose during the next forty-eight hours. Hypodermics consisting of atropin sulphate, $\frac{1}{250}$ grain; morphin sulphate, $\frac{1}{4}$ grain, and a little digitalis were administered every four hours for the first

twenty-four hours. The stomach was washed every four hours, but the vomiting of a dark foul-smelling fluid continued for seventy-two hours. The patient complained of great thirst, and after the first twenty-four hours was allowed moderate amounts of water by mouth. Ten days after operation a small abscess developed in the incision which promptly healed after the pus was evacuated. The patient left the hospital, April 24, weighing 93 pounds. She slowly recovered her strength and, June 1, resumed her housework and has continued doing housework to the present time—June 29. She now weighs 109 pounds and eats well but complains of abdominal pains after eating coarse food, pastries, etc.

HOMemade ICE TONGS FOR EXTENSION

R. F. STEVENS, M.D., EL PASO, TEXAS
Attending Surgeon, El Paso County Hospital

Ice tongs for extension may be easily and cheaply improvised from a pair purchased at a five and ten cent store, as here shown. To make them suitable for our use, the ends

Tongs for extension.

at *A* are cut off with a file, and new ones turned in, and then sharpened with the same tool or, better, an emery wheel. They are strong enough to sustain a pull of 30 pounds without bending. The opening at *B* is suitable for a wooden wedge, which may be placed after the tongs are adjusted, which will keep the points from approximating too closely and penetrating the bone too deeply. Another at *C* will keep the tongs from becoming unfastened in case anything should happen to the weight.

The Drop in the Birth Rate in France.—The *Bulletin Mch* quotes Rebillaud's annual report to the Conseil général on the child wards of the state in the département de la Seine. He stated that the number of births which was 73,599 in 1911 was only 47,189 in 1918, and during this last year the number of children abandoned by their parents was 3,149. The proportion of children thus turned over to public charity has risen from 4.99 per cent in 1911 to 6.99 per cent in recent years. The infant death rate, which was 1966 before the war, has risen to 25 per cent in 1918. The almost complete lack of vaccination has contributed to this high death rate. In 1912, the *Assistance publique* had 1,363 vaccines at its disposal, but in 1918 the number fell to sixty-five.

ABSTRACT OF DISCUSSION

ON PAPER OF DR. EUGENE S. TALBOT

(This issue page 805)

DR. G. V. I. BROWN, Milwaukee: The government has made a radical ruling during this war, distinguishing between the plastic surgeon and the facial surgeon who must have had a medical degree, and the dental oral surgeon who had only the dental degree. The National Dental Association is going to give quite a little consideration to this matter at its next meeting. I think that the question that Dr. Talbot deals with, and the suggestion that he makes in his paper of having an executive committee from this section attend meetings where there is discussion of dental education, representing in a more or less official way this section, is one that is worthy of thought.

DR. M. I. SCHAMBERG, New York: It becomes an absolute duty on our part, as a section, to take a definite position in the matter of the medical education of the dentist. At no time in the history of dentistry or medicine has it become so apparent to the medical profession, to the lay public, and to those of us who are vitally interested in this special feature, that medical education of the dentist and the complete medical education, is essential. I am convinced that there has been no period in the history of dentistry or medicine, when the opportunity is so favorable for this change. Men who take three or four years of study, which is almost paramount to the course in the medical schools, are entitled to a situation in this world, equal to the graduate of the medical school. It is asking too much of a man to spend that amount of time, and then be looked on as only obtaining partial medical culture. I would merely sound one note of caution in approaching the subject: that we do not put it quite in the way the chairman has. I think probably he might be induced to modify that term—of saying that they can have their mental training during the winter, and mechanical training during the summer, because that is almost a slap at mechanical training, which, after all, must be mental as well as manipulating.

DR. E. A. BOGUE, New York: There is in the dental profession, an idea of lack of recognition by medical men that is pretty general. As soon as our men are prepared the medical profession is prompt to recognize. If it were in the power of this section to encourage the younger men to go through the medical school it would be desirable. I knew pretty intimately Sir John Tomes and J. Smith Turner, who are responsible for the dental law of England; yet, with all the care which was given by them and their friends, the unqualified practitioner in number surpasses the other practitioners in England today. There are many in England to come up to the level which has been formed by our well qualified men during the war.

DR. FREDERICK B. MOORHEAD, Chicago: One does not need to look far to discover the trouble in dental education. The whole fault lies in the organization of a separate training for dentists. The dentist should receive, in a large measure, the same training as the physician, and dentistry will never be a satisfactory component of medicine until the dentist and physician are on an educational parity. To bring about the necessary change in dental education, it will require several years and must be done by evolutionary rather than devolutionary methods. We face a condition, and not a theory, in the premises. The people must be cared for in the matter of dentistry, and with the increasing knowledge on the part of the layman of the dangers of mouth infections, there is going to be a corresponding increased demand for dental services. To meet this demand more dentists will be needed. It would seem, therefore, that the first responsibility in dental education is not to decrease the output of dentists, but strengthen the dental curriculum to a point which will bring about a change of character in the dental students. We have at present, a four year curriculum with a high school graduation for admission, and in 1921 the better dental colleges of the country will require one year of college for admission to the dental curriculum. This will necessarily decrease the

output of dentists somewhat, and the requirement of one year of college for admission will probably have to stand for a number of years at least before any additional steps can be taken with safety. As soon, therefore, as the supply or demand will warrant, two years of college should be required for admission to the dental curriculum, which will place the dental student and the medical student on a basis of equality. When this step has been reached the first two years in dentistry and medicine may be identical. At the end of this period the dental student may undertake special training, and the medical student may also select his own special field of practice. A degree in medicine should then be conferred on both groups. We have before us an exceedingly difficult task, which must be faced with considerable thought and care. The supply must not be reduced seriously, and yet at the same time the training of the dentist must be of a different character if he is to functionate as an intelligent part of the medical program. It may be true that the question is too large for any early solution, and that we shall have to arrange for the special training of persons who will practice dentistry from a medical standpoint purely, and continue to train students for the general practice of dentistry as in the past.

DR. W. C. FISHER, New York: We speak of requiring a one year course in college. The Council on Medical Education, in their report, emphasize one great point: That there was one year of the four years in the high school that could be saved; and it was the consensus of opinion of many of the faculties, that the first year in college is almost a wasted year. If you are going to ask one year college education as a requisite of entrance to the dental college, you are asking a man to spend a year almost wastefully because that first year in college is a year of finding oneself. The Council on Medical Education thought that they must stop adding years to the time when a man may take his degree; that the limit has not only been reached, but it has really been passed; that they must now endeavor to go back to the preliminary education, and cut off years from that. This differs distinctly from Dr. Moorehead. If the young man is capable of going to college from high school, he is capable of going to medical or dental college. The medical faculty could exercise over these students the same care in their dental and medical colleges that they obtain in the schools of letters.

DR. ARTHUR D. BLACK, Chicago: I think that no matter from what angle we discuss this question, we must eventually come back to the ground on which Dr. Talbot has stood for all these years, and that is that the education of the dentist must be practically the same in its foundation work as that of the physician. I believe there is no question in the minds of most men who are interested in medical education, but that it would be thoroughly practical to cut out a year somewhere in the high school, or possibly in the grade school, and thereby bring a man up to entrance to the medical school a year earlier. In proposing to do so, we can not overlook the fact that a comparatively small percentage of high school graduates enter college, so that our problem is a side issue with those who are in charge of the elementary schools. I only mention that to emphasize the complexity of the problem that we have before us. In the management of our public schools, educators seem to be gradually coming to the realization that a year cut off for everybody, would be to their advantage, and eventually this may be brought about.

I would like to emphasize what Dr. Moorehead has said of the necessity of this being an evolutionary matter, and to impress the fact that it will take a good many years to accomplish our present objective. Suppose, for example, that the dental schools require one year of college for entrance in 1921, and that possibly in 1925 they require two years of college; that means it will be 1929 before we have our first graduates of a dental school on a parity with the graduates of the medical schools of today. It seems like a long time in advance, and yet that is the very earliest time within which the change can be made. Nevertheless, if we look backward for a period of ten, fifteen or twenty-five years, I think we can not help but realize that we have been making progress in all these years, and we are going to continue.

DR. CHARLES R. TURNER, Philadelphia: I feel that dental education has a present plotted out for itself, the same program that it has ever plotted out for itself. Dental prestige in America came, of course, originally from the development of the mechanical or the manipulative side. It was that, of course, which brought it to the attention of the practitioners of this profession in other parts of the world; in fact, for many years, that was "American dentistry." That is all there is to it; and that very thing has been our undoing. We have hitched our wagon to that thing for too long a time, so that, as we all know perfectly well, we are now beginning to realize that it has blinded us to a proper appreciation of the vital relationships of these things. Now we have within the last few years been paying particular attention to trying to correct that thing, but attaching greater significance to what may be called the vital relationship of dental operations; and it has been along that line that dental education has been working in the last few years. We must remember that the dentist must not only have knowledge, but he must have skill. It is wise for us to bear that phase of the matter in mind, and I must confess that I am disposed to feel that the training of the fingers should start as early as possible.

DR. EUGENE S. TALBOT, Chicago: I brought out in my paper the vital points that we have got to consider immediately, the points that I have stated in the paper have been known from a pathologic point of view for a great many years, and I have occasionally, from time to time, called the attention of the profession to those vital things in pathology, the statement I made more than thirty years ago, that dentistry was producing more pathology than any one cause is beginning now to be recognized. The vital points in this paper have got to be considered right away, for the reason that we are producing more pathology than the patient; that is to say, nearly every operation that is performed in the mouth produces and leaves later in the mouth a pathologic condition. We have got to immediately change our methods of teaching. The whole thing lies in the dental school. We have got to teach pathology, and make mechanics a second consideration.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

BENZYL ALCOHOL (See New and Nonofficial Remedies, 1919, p. 52).

Benzyl Alcohol (Van Dyk).—A nonproprietary brand of benzyl alcohol complying with the tests and standards for benzyl alcohol.

Manufactured by Van Dyk and Co., New York City.

CINCHOPHEN.—A nonproprietary name applied to phenyleinchonic acid (Acidum Phenyleinchonicum, U. S. P.).

Actions, Uses and Dosage.—See under Phenyleinchonic Acid and Phenyleinchonic Acid Derivatives (New and Nonofficial Remedies, 1919, p. 226).

Cinchophen-Abbott.—The Abbott Laboratories have adopted the name cinchophen for the product accepted as phenyleinchonic acid-Abbott (see New and Nonofficial Remedies, 1919, p. 227).

Cinchophen-Morgenstern.—Morgenstern and Company have adopted the terms cinchophen and sodium-cinchophen-water for the products accepted as acid, phenyleinch-Morgenstern and sodium phenyleinch, water-Morgenstern (see New and Nonofficial Remedies, 1919, p. 227).

Cinchophen-Calco.—A brand of cinchophen. It complies with the standards for Acidum Phenyleinchonicum, U. S. P. Manufactured by the Calco Chemical Company, Newark, N. J., U. S. Patent No. 1,075,171 (Oct. 7, 1913; expires 1930), No. 1,192,362 (Sept. 5, 1916; expires 1933), No. 1,086,881 (Feb. 10, 1914; expires 1931) under license from the Chemical Foundation, Inc.

THE INHERITANCE OF ACQUIRED CHARACTERS

There is something almost dismal in the currently popular theories of heredity, so far as they apply to the human race. If we complacently accept the mendelian doctrine, the outcome of all matings and consequently the hope for the future seems to depend on the almost inflexible mathematical distribution of unit traits through the fortuitous unions that occur. Education, under this doctrine, cannot create capacity; it can merely enable an individual to utilize more fully his inherent potentialities. Training does nothing more than give an opportunity to latent capacities. Hundreds of experiments have demonstrated that acquired characters cannot be transmitted. Neither accidental mutilations nor intentional operative alterations in the organism become transmitted to the offspring. The children of parents with amputated limbs continue to be normal in respect to these appendages.

Fischer¹ has recently urged the reacceptance of the theory of inheritance of acquired characters, interpreting the latter in the lamarkian sense. He submits that mutilations are not acquired in the true functional sense—they are inflicted. Truly acquired characters are those developed in a functional way through the effort or performance of the individual concerned. In urging this point of view, Redfield² has pointed to the records of horse breeding, one of the fertile fields for the accurate study of heredity. It is claimed that training, that is, functional activity, is indispensable to secure acceptable inheritance. Speaking of race-horses, Fischer says that "the winners of a new generation are the progeny of hard working parents, the losers the sons and daughters of the retired best families." In the domain of dairy cattle the functional character of milk production seems to be enhanced with each successive calf in the record families. Early born calves are far less likely to be great producers than are the later off-spring of the same cows. The

youngest daughters of the oldest cows are shown by experience to tend to be superior.

The corollary to this contention that performance is not without influence in heredity has been sought by Fischer¹ in the pages of human history. Insisting that, other things being equal, a father or mother of maturer years is more definitely possessed of acquired mental character than a younger one, Fischer maintains the thesis that the offspring of older parents have exemplified in a striking way the inheritance of the acquired characters. According to his statistics, if the probability of being eminent when born of a father between 35 and 40 is taken as unity, the probability if born at 25 is less than one fifth as great. Ascending the age scale, the probability at from 50 to 55 is five times that at from 35 to 40, and over 60 it is ten times that.

Statistics on human heredity are notably difficult of analysis. The study of the inheritance of character, such as mental traits or degrees of eminence, which cannot be measured in customary ways, is beset with many entanglements. But since the current rock-bound conceptions of inheritance and its limitations fail to satisfy the searcher for "new hopes," every attempt to find a more flexible possibility of human betterment than the current eugenics theories afford will find some hearing.

PROTEIN SYNTHESIS: A CHAPTER IN TISSUE REGENERATION

In the higher forms of life, such as man, the metabolic processes never become dormant. Energy is required every minute of every hour during life to enable the indispensable functions to be continued. Consequently, whenever the food intake is insufficient for the needs of the body, the organism is compelled to "live on itself." Loss of protein is an invariable accompaniment of this enforced squandering of the hoarded resources; but it has long been recognized that such a loss can be diminished or even prevented by adding other foodstuffs to the diet. The student of nutrition has accordingly learned to speak of the "protein-sparing action" of these nutrients, among which carbohydrates rank first in this respect.

How do carbohydrates "spare" protein? Do they merely act by furnishing energy which directly replaces protein that would otherwise be disintegrated for immediate use? If so, the explanation of the protein-sparing action or protein-protecting power of carbohydrate would be that it checks the destruction of tissue protein at its source. If this were the correct and sole interpretation of what carbohydrate feeding accomplishes, it ought to be "protective" toward protein only so long as the fuel value of the food is insufficient. But an abundance of carbohydrate may even lead to protein storage when the energy intake is

¹ Fischer, M. H.: *The New Hope in Heredity*, The Century Co. Review, 112:273 (April-June) 1919.

² Redfield, L.: *Dynamic Evolution*, New York, G. P. Putnam's Sons, 1914.

otherwise adequate. Hence, as Sherman¹ clearly points out, the fact that addition of carbohydrate or fat to a diet already sufficient may cause an actual shortage of protein indicates that the protein-sparing action of these foodstuffs involves something more than merely the question whether the body needs to burn its stored protein as fuel.

Another explanation for the favorable effect of carbohydrate feeding on protein metabolism has been sought in the suggestion that sugars or their derivatives in some way intervene in the reconstruction of protein fragments into amino-acids and new protein. From this standpoint, protein might be spared by carbohydrate, not because its breakdown is prevented at the source, but because the carbohydrate helps to fix and thereby conserve disintegration end-products so that they are rendered available for the building of new protein in the body. In favor of this view, Whipple² and his associates of the George Williams Hooper Foundation for Medical Research, University of California Medical School, have cast new experimental facts. Their observation that a suitable chloroform anesthesia during a fasting period will provoke a type of necrosis that may lead to the destruction of one half or more of the liver tissue, and that under favorable conditions complete repair can be effected in a few days, has given an opportunity to study the rôle of diet in the reconstruction. The exceptional character of this restitution is indicated by the fact that the tissue may be renewed at the rate of from 100 to 150 gm. (3 to 5 ounces) per day, equivalent to the construction of a mass of liver cells the size of the normal spleen or kidney every twenty-four hours.

The report states that liver repair is much more rapid and complete on a sugar or high carbohydrate diet than it is on starvation. In fact, an injury of one half of each liver lobule may be completely repaired in nine days on a sugar diet, but only 50 per cent. repaired under fasting conditions. In such cases, protein must obviously be synthesized on a large scale. Hence Davis, Hall and Whipple insist that their observations furnish convincing evidence that the "protein-sparing action of carbohydrate" in this instance is a true conservation of protein cleavage products. This evidence, they add, cannot be explained as protein sparing at the source or as simple inhibition of protein autolysis or catabolism.

Fats, on the other hand, do not aid liver regeneration in the way just noted; nor is meat as favorable to rapid repair as is a rich carbohydrate diet. Davis and Whipple,³ who ascertained these facts, recognize that

fat may spare protein in ordinary metabolism. When fat is burned as fuel, protein is protected from destruction. But since fat lends no essentially superior efficiency to the repair processes after liver necrosis in the way that sugar does, we must conclude, with the latest investigators, that fat acts as a "protein sparer" not by conservation of end-products and reconstruction of new liver tissue, but by some protecting action at the source of tissue catabolism. This defines what they conceive to be a clean-cut difference in the metabolism of fat and carbohydrate relating to protein construction and destruction. Since heavy protein feeding has been found most favorable to the regeneration of serum proteins,⁴ it remains to be ascertained whether the interesting observations made on a large organ like the liver are peculiar to it or apply to metabolism in all parts of the body. Equally undemonstrated is the suggestion² that the liver may be the place in which the union of carbohydrate and protein split products may be made permanent, whether the resultant products are to be used in the liver or elsewhere in the body.

THE TREATMENT OF ACUTE EMPYEMA

Among the interesting developments in the field of surgical therapy in the past two years, few have exceeded that of empyema of the chest in the thoroughness of the study to which it has been subjected, and in the applicability of the results of such study to the problems of civil life. In the prewar days it had been accepted that the proper treatment of an accumulation of pus in the pleural cavity was free drainage by thoracotomy, with or without rib resection, and usually without irrigation, supplemented by the use of breathing exercises and mild calisthenics to encourage expansion of the lungs. A few surgeons attempted further to supplement thoracotomy by the use of a suction apparatus applied to the drainage tubes, but without sufficient success to encourage general adoption of this measure.

The objections to simple thoracotomy were in general twofold: 1. It permitted collapse of the lung through the equalization of air pressures within and without the pleura. This collapse occasionally became permanent, necessitating secondary operations of dubious prognosis for the obliteration of the discharging cavity thus produced. 2. The abundant drainage for the first few days or weeks following operation frequently became a great burden to nurse and patient. As these objections were of sufficient importance to stimulate interest in any method that promised to obviate them, the results of the efforts of the Army Medical Corps in the treatment of large numbers of postinfluenza empyemas have been eagerly followed. Early in

the epidemic, thoracotomy and drainage were instituted as soon as the diagnosis was made, with a very high resultant mortality. Thereupon three general plans of treatment were developed: 1. A revival, with modifications, of the old Thiersch or closed method in which a catheter is passed into the chest through a trocar and the trocar removed, the catheter being anchored to the chest wall by adhesive plaster; to the outer end of the catheter is attached a collapsible rubber tube, the free end of which is inserted into a bottle of water. "The theory is, that when the patient expires, the pus runs out through the tube, and on inspiration the collapsible walls of the tube are sucked together and prevent the entrance of air, and cause negative pressure in the chest, favoring expansion of the lung."¹ 2. The Thiersch method plus the instillation of antiseptic solutions, chief of which were surgical solution of chlorinated soda (Dakin's solution) and formaldehyd glycerin. 3. Thoracotomy with free, open drainage plus irrigation with antiseptic solutions.

Conflicting reports have appeared concerning the efficacy of each of the numerous modifications suggested, but at last we seem to have returned to the prewar conception of the necessity of free, open drainage in the treatment of true empyema, the principal remaining bone of contention being that of the instillation of antiseptic solutions into empyema cavities. Dodge² is emphatic in his declaration against the use of antiseptic irrigations, maintaining that "irritating antiseptics," such as Dakin's solution, not only do not assist in removing fibrin masses, but actually cause a fibrinous exudate to appear on the pleura, binding the lung down and so greatly interfering with the obliteration of the empyema cavity. According to Dodge, if the drainage opening is of sufficient size and correctly located, nothing more is essential; in exceptional cases, irrigation with a bland solution, such as physiologic sodium chlorid solution, may be desirable. The majority of reports speak favorably of Dakin's solution in empyema, some going so far as to regard it as essential. In some instances it certainly appears to have greatly shortened convalescence.³

In a discussion of this subject it should never be forgotten that empyema occurring in influenzal pneumonia is quite different, pathologically, from the post-pneumonic empyema with which we are familiar in civil life.⁴ In the former, a purulent pleural exudate appearing within a few hours of the onset of pneumonia is of secondary importance to the pulmonary condition. If prompt thoracotomy is done, grave respiratory embarrassment is almost certain to fol-

low. The source of intoxication at this time is in the lungs, not the pleura. Treatment should be palliative—by aspiration. As the pneumonic process subsides, the pleural exudate may be absorbed without further treatment; if spontaneous cure does not occur, thoracotomy will be necessary, but should never be done while the pulmonary inflammation is active. Early thoracotomy was apparently an important contributing cause of the high mortality from empyema during the early months of the epidemic. In the case of empyema following lobar pneumonia, the pleural exudate becomes purulent late in the course of the pneumonia, and as a rule is then the sole source of the toxemia from which the patient suffers. The fundamentals of treatment in this condition are those of the prewar period.

PHYSIOLOGIC RELATIONSHIPS OF IODIN

The importance of iodine and its compounds for the proper functioning of the healthy organism is beginning to be appreciated. The rôle of the element to which reference is here made is a purely physiologic one—an influence quite distinct from the effects which have long been ascribed to iodids as they are used in large doses in human therapy. Most important of the newly recognized features is the relationship between the function of the thyroid glands and the iodine-containing material present therein. For example, Marine of Cleveland has observed that the amount of iodine is inversely proportional to the degree of hyperplasia of the gland; and when the hyperplastic condition becomes fully developed, scarcely a trace of iodine is left in the gland. When the hyperplasia gives place to colloid goiter, the iodine increases both relatively and absolutely. Moreover, it has been found that if an iodid is administered to an animal suffering from hyperplasia, the hyperplastic condition promptly disappears and the animal becomes normal.¹ We have also called attention to the recent observations of Marine and Kimball² on the efficacy of small doses of an iodid administered to schoolchildren living in goitrous regions, such as those about the Great Lakes in the United States. The fetal athyreosis observed in domestic animals in some of our Western states can likewise be averted by dietary administration of small quantities of iodine-bearing substances.

The minuteness of the quantities of iodine involved in these various physiologic functions has made it difficult to obtain accurate estimations of them. In the thyroid, where the element accumulates, the few milligrams of iodine present can be ascertained analytically; but the far smaller proportions which must be assumed to circulate from time to time incidental to their physiologic performance have eluded analytic

pursuit. Recently, through refinements in the methods for determining very small quantities of iodine, Kendall³ of the Mayo Clinic has estimated the amount in blood at approximately 0.015 mg. per hundred c.c. The content in the tissues is slightly greater—about 0.03 mg. per hundred gm.; in the liver it may reach 0.04 mg. per hundred gm. of this glandular organ. These statistics are of interest in indicating the extremely small amounts of iodine-containing compounds that seem to be essential for metabolic needs.

The crystalline compound thyroxine, which Kendall has succeeded in isolating from the thyroid gland and which he regards as the physiologic hormone of that structure, contains about 60 per cent. of iodine. According to numerous observations at the Mayo Clinic, 1 mg. of thyroxine increases the metabolic rate 2 per cent. in an adult person weighing approximately 150 pounds. Kendall estimates that this figure is in reasonable accord with the quantities of iodine actually found in circulation. It is asserted that if only a single administration of thyroxine is given, a demonstrable action may fail to be produced. Three or four successive daily administrations may be necessary in order to evoke evidences of hyperthyroidism. Kendall's explanation³ for this is found in his observations on the elimination of thyroxine from the body. He asserts that as much as 60 per cent. may be rapidly eliminated with the bile. In one instance 8 per cent. was found in the urine, so that a remaining one third of the hormone introduced may be assumed to have been taken up by the thyroid gland. This, Kendall says, indicates why the single administration does not produce a physiologic response. It is only the continued presence of the iodine compound within the body which results in the increase in metabolic activity. These findings have an obvious bearing on thyroid therapy.

Current Comment

THE JUNCTION OF URETERS AND BLADDER

A few years ago, it was customary to ascribe an ascending nephritis, following an infection of the bladder, to the reflux of bacterially contaminated urine through the ureter openings backward to the kidneys. An offhand consideration would make this seem to be the most plausible mode of transmission of infectious material from the lower to the upper parts of the urinary tract. Latterly, however, investigation has made it quite probable that the lymphatics may play an unsuspected part in this migration of microbial invaders. This view is strengthened by the accumulating evidence that the normal closure of the ureters is competent to prevent a reflux of urine toward the kidney. Recently, further support has been afforded by the investigations at the Physiological Laboratory

of the Johns Hopkins University by Satani.¹ He observed experimentally on animals that the bladder can be distended very fully and so maintained without any leakage into the ureter lumen. However, after destruction of the muscles of the bladder wall which cover the intraparietal part of the ureter, the ureter opening no longer functions so perfectly as a valve. Ordinarily, it appears, the distended bladder muscles over the ureter press this tube together closely so as to prevent reflux. Under normal conditions, then, a backward flow of urine cannot take place. In addition to the anatomic relations which bring about this physical prevention, Satani maintains that the physiologic activity of the musculature at the intraparietal portion of the ureter lends assistance. He refers to a layer of longitudinal muscle on the outer side, while the Waldeyer ureter sheath covers a portion of the medial side. The contraction of the former tends to close the orifice, and the contraction of the latter causes the lip-shaped upper rim to protrude. These mechanisms, according to Satani, assist to prevent the reflux of urine into the ureter.

ORTHOPNEA

Orthopnea is the term applied to the condition of certain patients suffering from dyspnea (and notably from cardiac dyspnea), who cannot breathe as comfortably when lying as when sitting. The reason for the advantage of the upright posture has been a matter for conjecture for some time. Recently Pearce² summarized the uncertainty by stating that the greater vital capacity in the upright position, the favoring of the return of the venous blood from the cerebral vessels because of the enlarged thoracic cavity, and the increase in the reserve air in the lungs are all factors to be considered. A more rational explanation of the phenomenon of orthopnea has, however, latterly been offered by Haldane, Meakins and Priestley,³ who have shown that anoxemia, or deficiency of oxygen in the circulation, and shallow breathing are interrelated in surprising ways.⁴ Excess of carbon dioxide causes in the main deepening of respiration; lack of oxygen causes in the main shallow and quick breathing. Now the recumbent posture tends to accentuate any irregularity that may exist in the expansion of the lungs. Shallow breathing causes uneven ventilation of the lungs. The irregularities are less marked when the patient is in the upright position. As the English observers interpret the situation, there are persons in whom the ineffectiveness of the circulation reaches such a degree as just to make the respiratory center begin to respond to anoxemia, with its attendant shallow respiration. The patient may be fairly comfortable so long as he remains at rest in an upright position. As soon as he lies down, the irregularity in the expan-

sion of the lung alters his condition for the worse. "He still has the abnormally great drain of oxygen in the systemic blood, and in addition the oxygenation of the blood in the lungs is no longer so efficiently carried out and consequently the arterial blood carries a less quantity of oxygen than before. There is, therefore, a condition in which an increased call on the oxygen carried by the blood is coincident with a diminished saturation of the hemoglobin in the arterial blood with oxygen. Naturally, therefore, it is to be expected that there will be an exacerbation of symptoms when the patient lies down." If, as Haldane, Meakins and Priestley argue, orthopnea is due to shallow breathing caused by and intensifying anoxemia, the indication for a method of relief is clear. Oxygen should be added to the inspired air. It is interesting to note that such interferences with abdominal or thoracic movement as may be caused by corsets can hamper the even expansion of the lung sufficiently to induce periodic breathing, which is a sign of oxygen deficiency. In this case, too, the effects are more conspicuous when the person is lying down.

MODEL ORDINANCES FOR VENEREAL DISEASE CONTROL

The widespread efforts to suppress venereal diseases have necessitated the adoption by many of our cities of ordinances for this purpose. In order to aid cities desiring to legislate on this subject, the U. S. Public Health Service, with the assistance of the Law Enforcement Division of the War Department, has prepared and issued a compilation of suggested and adjudicated ordinances which have proved successful in combating venereal diseases.¹ These include a general venereal disease control ordinance, and special ordinances regulating the licensing of hotels and rooming houses, public vehicles and public dance halls, an ordinance prohibiting advertisements of venereal disease nostrums, and ordinances for the regulation of restaurants and grill booths, prohibiting the sale of venereal disease medicine except on prescription, and regulating "massage parlors." Cities desiring to enact ordinances on these subjects are advised to secure in each case the advice of competent local counsel for changes in form or substance as may be required by special constitutional, legislative or charter considerations. Each of the model ordinances has been in operation in different cities and, it is stated, has been found effective for the particular purpose for which it is drafted.

APPRENTICESHIP IN THE CARE OF THE BABY

Apprenticeship in practical work is an indispensable part of a well rounded training in more than one field of professional education. Apprenticeship may become something more than mere vocational training. It represents the opportunity to apply in concrete ways the conclusions derived from a theoretical study in some field of learning—of subjecting to the test of experience the dicta of the textbook and the lecture

hall. In medicine, apprenticeship found its application in older days through the service which a young man "reading" in the office of a physician was able to render under the tutelage of his professional master. Today it is exemplified in the experience gained by the medical student through his hospital internship or dispensary service. In the domain of home economics, which has become so firmly entrenched in the education of American women, the practice house has afforded something comparable to what the hospital offers to the medical student. Recently the varied activities in the practice houses of one large educational institution, the University of Minnesota, have been diversified still further by affording opportunities to observe as well as to assist in the care of infants.² The latter are secured from orphanages. This form of apprenticeship in the study of the homemaker's job is an innovation which deserves to be watched with interest. The attempt to train teachers of future homemakers thus fundamentally ought to be no more difficult than the introduction of a real medical apprenticeship has been.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending September 5, there were 7,176 officers in the Medical Corps, a decrease of 359 from the previous week. The Medical Reserve Corps contained 3,370. The total number of physicians discharged since the beginning of the war is 24,947.

Dr. Oman Becomes Fleet Surgeon

Charles M. Oman, Commander, M. C., U. S. Navy, has been appointed aid to the commander in chief of the U. S. Atlantic fleet, and fleet surgeon. During the war Commander Oman served as commanding officer of U. S. Hospital Ship *Comfort*, and later of U. S. Naval Base Hospital No. 1, Brest, France. He has been recommended for the Distinguished Service Medal.

Favors Universal Military Training

The National Tuberculosis Association has notified the United States Senate that it is in favor of universal military training legislation. Senator James W. Wadsworth, chairman of the Senate Committee on Military Affairs, has presented the following resolution to the Senate:

Be it Resolved, That the National Tuberculosis Association, through its executive officers, take immediate steps to secure the cooperation of all other great health organizations, especially the American Medical Association, and state and territorial health officers, in placing before the American people a united demand for the adoption of universal military service as a public health measure.

The resolution was referred to the Senate Committee on Foreign Affairs for consideration.

Amendments Offered to War Risk Insurance Act

Under date of August 26, a bill was introduced by Mr. Sweet in the House of Representatives, to amend and modify the War Risk Insurance Act. The amendment provides for the appointment of a director of the Bureau of War Risk Insurance, to conduct the bureau. It defines "active service"; increases the amount of compensation for disability; enlarges the class of beneficiaries so as to include in addition to those already included, uncles, aunts, nephews, nieces, brothers-in-law and sisters-in-law, of the insured. Another section provides that the bureau may make provision in the contract for converted insurance for optional settlements to be selected

¹ *Veneral Disease Bill*, J. U. S. P. H. S.

² The information here given was derived from *Home Economics Field Note*, The Vocational Summary 2:69 (Aug.) 1919.

by the insured, whereby the insurance may be payable either in one sum or instalments of thirty-six months or more. The bill bears the endorsement of the Secretary of the Treasury, who urges that all of the amendments shall be made at the earliest possible moment. In the report of the committee favorably referring the bill back to the House, is an interesting table as to what constitutes disability, with percentage. For example, epilepsy with fits occurring daily is 100 per cent. disability; fits occurring periodically at intervals of two to four days is 80 per cent.; from eleven to thirty days is 40 per cent., and at intervals exceeding thirty days, 20 per cent. The entire human body is thus classified as to percentage of disability of various parts.

Personal News of the Services

Edgar E. Hume, Lieut.-Col., M. C., U. S. Army, who is at present on duty as medical director of the Red Cross Mission to Serbia, has been given the Serbian Order of the White Eagle.—Charles E. MacDonald, Major, M. C., U. S. Army, who has been on duty in the Evacuation Post at Hoboken, has been ordered to duty as surgeon on the U. S. S. *Agamemnon* which has been turned over to the Army, and sailed for Brest, September 3.—Roger Brooke, Col., M. C., U. S. Army, was guest of honor at a luncheon given by the National Tuberculosis Association, August 26. He gave a comprehensive talk on the discoveries in the Army, as to the prevalence of pulmonary tuberculosis in the male population when the selective service law was put into operation, and the steps taken by the Army for the relief and cure of men so affected.—A life size oil painting of Major-Gen. Merritt W. Ireland, Surgeon-General, made by Lieut. Maurice L. Bower, Sanitary Corps, has been hung in the hall of the main stairway in the Army Medical Museum, Washington, D. C.

Awards of Distinguished Service Medal

The Distinguished Service Medal has been awarded by the commander in chief of the American Expeditionary Forces by order of the President, to the following officers of the American Expeditionary Forces for exceptional meritorious and distinguished service in France, Belgium and Russia.

WALTER AUGUSTE YVON DUBAIL, General, French Army. "Through his distinguished efforts one of the largest hospitals in Paris was made available for the American E. F."

EMILE CASTELLI, Colonel, French Army. "Advisor to the Medical Service of the American E. F., assisted in preparation of comprehensive hospitalization program."

EDOUARD CHARLES LAVAL, Lieut.-Col., French Army. "Member of the 4th Bureau, French Army, rendered invaluable service in connection with front line medical tasks in the American E. F., and by co-operation, aided us in procuring hospital facilities."

PIERRE FELIX MORTIER, Major, French Army. "Medical member of the French Mission at General Headquarters, American E. F., labored in medical section of Central Bureau of Franco-American relations, labored with conspicuous success in interests of the sick and wounded."

MICHAEL D. BERGER, Comdt., French Army. "While serving in D. T. M. A. was in personal charge of practically all movements of troops and hospital trains."

TINARDON, Commandant, French Army. "Member of the 4th Bureau, Central Staff, French Army, rendered invaluable service to the American E. F., in connection with selection of suitable sites for depots and hospitals."

PAUL ALBERT JOSEPH PETIT, Commandant, French Army. "Attached to the Medical Section Central Bureau of Franco-American Relations, and later at G. H. General Headquarters, American E. F."

C. H. BURKCHIAELL, Lieut.-Gen., British Army. "Director General of Medical Service, British E. F., provided adequate hospitalization and evacuation facilities for sick and wounded of American troops serving with British Armies."

Sir T. H. J. C. GOODWIN, Lieut.-Gen., British Army. "Surgeon-General, British Army, placed at disposal of American division serving with the British forces all evacuation and hospitalization facilities at his command."

JAMES L. BEVANS, Colonel, M. C., U. S. Army. "Served with distinction as chief surgeon of 3d Army Corps."

JAMES D. GLENNAN, M. C. "In charge of hospitalization division in office of chief surgeon, directed establishment, equipment and operation, as well as evacuation service of all American hospitals in France."

ELMER A. DEAN, M. C. "Came to France with base hospital unit, which he established, later organized and commanded first large hospital center at Bazailles."

JOHN W. HANMER, M. C. "Commanding officer of Evacuation Hospital No. 1, displayed high professional attainments and loyal devotion to duty, subsequently chief surgeon, 4th Army Corps."

JAMES A. MCCOY, M. C. "Served with conspicuous success as commanding officer, American Red Cross Hospital No. 111, at Juncy-sur-Nievre and Chateaufort, from June to August, 1918."

CHARLES R. REYNOLDS, M. C. "Division Surgeon, 72nd Division, chief surgeon 6th Army Corps and later chief surgeon 2d Army, displayed qualities of leadership, high professional attainments and rare judgment."

ROBERT H. PIERSON, Col., M. C., U. S. Army. "For exceptionally meritorious and distinguished services. He served as division surgeon of the Fifth Division, from its organization until the close of hostilities, when he became chief surgeon of the Sixth Army Corps. Due to his sound judgment and efficient direction of medical personnel, gas casualties in his division were reduced to a minimum. By his resourceful methods in combating disease he prevented the firing lines from being depleted at a critical time, maintaining a high standard of combat strength efficiency."

C. H. BURKCHIAELL, Lieut.-Gen., C. R. C., M. C. G. "For exceptionally meritorious and distinguished services. As director general of Medical Service, British Expeditionary Forces, he displayed untiring zeal, eminent talents, and broad experience in providing adequate hospitalization and evacuation facilities for the sick and wounded of the American Troops serving with the British Armies. His individual efforts counted largely in enabling the American Medical Service to function efficiently."

Distinguished Service Cross Awards

A posthumous award of the Distinguished Service Cross has been made in the case of Ralph E. Powers, Lieut.-Col., M. C., Akron, Ohio, attached 337th Ambulance Company, for service at Ust. Padengia, Russia, Jan. 20 to 23, 1919.

The Distinguished Service Cross has been awarded by the commanding general, American Expeditionary Forces, by direction of the President, to the following named officers:

FRED C. ALBRIGHT, Capt., M. C., U. S. Army, 353d Infantry, Garland, Kan. "For extraordinary heroism in action near Xunmes, France, Sept. 13, 1918. When the battalion on the left of his own met with such heavy fire, as it was attempting to take its position, that it was forced to withdraw, leaving many wounded men behind, Captain Albright, with fearless disregard for his own safety, went to the adjoining area, and, under continued heavy artillery fire, cared for all the wounded who had been left there."

JOSEPH A. MENDELSON, Lieut., M. C., U. S. Army, Sanitary Detachment, 365th Infantry, Washington, D. C. "For extraordinary heroism in action near Ville Savoy, France, Aug. 15-16, 1918. During a heavy enemy bombardment with gas and high explosive shells, Lieutenant Mendelson worked for more than three hours, picking up wounded and gassed men and securing their evacuation, being forced to remove their gas masks in order to accomplish this work. Though he was almost exhausted from fatigue, he then proceeded to the aid station of another battalion and assisted in treating hundreds of men. Though he was himself suffering from the effects of gas, he refused to go to the hospital upon the completion of this work, as all the other medical effects had been evacuated."

JOHN P. D. LUMLEY, Capt., M. C., U. S. Army, 357th Infantry, Kampsville, Ill. "For extraordinary heroism in action in the St. Mihiel offensive, September 14, and near Badon, France, Nov. 10-11, 1918. In the St. Mihiel offensive he showed marked personal courage advancing his first aid station with the front line. Near Badon he maintained a dressing station far to the front, under terrific artillery and machine gun fire, showing absolute indifference to personal safety that he might aid the men on the firing line during heavy gas bombardments."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF VALUE OF SOME OR LESS CLINICAL INTEREST, SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

DISTRICT OF COLUMBIA

Personal.—Dr. Frank Abbott, medical inspector of the District health department, has been appointed superintendent of the Washington Asylum Hospital.

ILLINOIS

Midwife Fined.—Mrs. Anna Tutlin, Rockford, who is said to have been placed under bonds recently, following the illness of a young woman to whom she is said to have given an abortifacient, is reported to have been fined \$50 and costs, September 4.

Personal.—Dr. Charles F. Lynch, Chicago, has been appointed health officer of Aberdeen, S. D.—Dr. William R. Marshall, Clinton, has been elected president of the Black County Anti-Tuberculosis Association.—Lieut. Col. George de Tarnowsky has returned to Chicago after an extended service abroad with the Army in the war zone and with the American Red Cross in Poland and southeastern Europe.

Treatment of Socially Unfit.—The Chicago Municipal Morals Commission, August 30, inaugurated a movement to rid the city of vice and venereal disease. The plan provides for the segregation of all infected persons and a fund of \$120,000 appropriated by the state and city government has been made available for carrying on the work. It is proposed to organize a special vice squad, and all suspects will be sent to the Iroquois Memorial Hospital for examination, and if found affected will be held until cured. The president of the county commissioners of Cook County has been asked to set aside a large ward in the Cook County Hospital for the treatment of these cases.

Illegal Practitioners Fined.—The Illinois Department of Registration and Education arrested Mrs. Lulu C. Parmenter of Galesburg and Stefan W. Sobolewski of 1111 North Marshall Avenue, Chicago, for treating human ailments without a license. They are said to have been fined, respectively, \$25 and costs and \$50 and costs.—It is reported that D. H. Prince of Love's Park was arrested recently by the Illinois Department of Registration and Education for practicing medicine without a license and was fined \$100 and costs. Prince was charged with diagnosing an ailment of a young woman in Rockford as goiter and was said to be receiving for medicine a large part of the money contributed by the charitable workers of Rockford for the support of the family of the young woman. At the trial Prince was compelled to return all the money he had received for his so-called professional treatment.

INDIANA

Personal.—Dr. Fred W. Terflinger has resigned as superintendent of the Northern Hospital for the Insane, Logansport, and was succeeded by Dr. Paul E. Bowers of Whittier, Calif., September 10.

Prisoners Treated by Public Health Service.—All prisoners in the Marion County Jail, Indianapolis, will hereafter be examined for venereal disease and treated for the same by the United States Public Health Service clinic.

School Inspectors Appointed.—The Indianapolis Board of Health has appointed the following physicians as inspectors of public schools: Carrie J. Reid, Martha J. Smith, George J. Martz, James M. Smith, Joseph L. Conley, Albert W. Miller, Colin V. Dunbar, Charles F. Bayer, William Wise and Clarence N. Harris.

LOUISIANA

Tuberculosis Hospital Not Health Menace.—In a suit brought by Le Bourgeois et al. to enjoin the city of New Orleans from establishing and maintaining a tuberculosis hospital in the city, one of the plaintiffs alleged that the hospital would endanger the health of those living in the vicinity. The supreme court, however, does not take this view. In its decision it states: "If it were proved with certainty that this hospital would endanger the health of this

Mortality in Portuguese Army.—Dr. Antonio Barradas reported at the medical congress held recently at Madrid that the Portuguese army on duty in France during the war formed a total of 75,000 men. Of these 75,000, 2,000 died, 1,460 in battle, 340 of disease and the rest are unaccounted for. The Portuguese troops in East Africa lost 6,000 men by disease and only 1,000 in battle. The wounded in France numbered 6,460, of whom 1,460 died. Those disabled more or less permanently amounted to 7,000, 45 per cent. of the disabilities being due to tuberculosis and 340 dying of this disease. The vaccination against smallpox and typhoid resulted in controlling these diseases so that there was no smallpox among the troops and only five deaths from typhoid. The Portuguese physicians did their duty in the war, 300 out of 3,000 in the whole country serving in France.

plaintiff or his family, perhaps a case might be presented for judicial interference. But the very opposite is conclusively shown by the evidence, which is all one way to the effect that a well kept tuberculosis hospital is not a menace to the health of the people living in its vicinity and the presumption is that this hospital will be well kept. . . . Our conclusion is that the suit is groundless in so far as it is sought to be founded on the apprehended injurious character of the proposed hospital."

MARYLAND

Personal.—Dr. John F. Doucher, Baltimore, expects to sail, October 2, from Vancouver for Asia, where he will remain for six months as a member of the commission on Christian education in the missionary field.—Dr. Eli Marshall, Jr., Baltimore, has been made professor of pharmacology in Washington University Medical School, St. Louis.—Dr. Eugene H. Hayward, Baltimore, who went to France early in the war with the University of Maryland Base Hospital Unit and served also with the Army of Occupation in Germany as major, has returned to his home in Baltimore.—John W. Wheeler, who has been in charge of the eye department at U. S. Army General Hospital No. 2, Fort McHenry, Baltimore, has received his discharge and has returned to his home in New York City.

Clinic in Need of Funds.—The government social clinic at Mersey Hospital, Baltimore, established in October of last year, will have to cease functioning if funds to support it do not come from some source. The United States government, through the public health service, is ready to repeat last year's appropriation of \$14,200, provided the state furnishes an equal sum, making a total of \$28,400 to fight social diseases in Maryland for one year. Dr. Anton G. Rytina, Baltimore, is director of the clinic and with a staff of twelve physicians, a secretary, a woman social service worker and a nurse, he now treats more than 500 men and women in this clinic. He works under the auspices of the state board of health and the United States Public Health Service. Dr. Rytina believes that the state legislature would not hesitate to appropriate the necessary \$14,200 to match the national government's appropriation for the state, but declares the fight against these diseases cannot wait until next January, when the legislature convenes. The money is needed at once.

MAINE

Personal.—Dr. Leverett D. Bristol, Augusta, state health commissioner, has been elected dean of the College of Medicine of the University of Tennessee, Memphis, and will assume his duties this month.—Dr. Edwin D. Jaques, South Berwick, has been nominated as medical examiner (coroner) for York County.

MASSACHUSETTS

Personal.—Dr. Leon A. Alley, Rutland, has been made acting superintendent of the State Sanatorium, Rutland, succeeding Dr. Ernest B. Emerson, resigned in order to accept a position in a hospital in Brockton, Mass.

Lowell and Cutter Lectures.—Harvard University announces that Dr. Thomas M. Legge, chief medical inspector of factories in Great Britain, will give a course of Lowell lectures and the Cutter lectures in preventive medicine during the coming year under the auspices of the School of Public Health of Harvard University and the Massachusetts Institute of Technology, and the division of industrial hygiene. Dr. Legge will lecture in Boston, November 18, and ensuing dates on the following subjects:

Twenty years' experience of the Nutrition of Industrial Diseases; Twelve Years' Experience of Workmen's Compensation Act and Industrial Diseases; Medical Supervision in Factories; Industrial Poisons and Their Prevention; Anthrax; Fumes and Gases; Industrial Fatigue; Industry as a Subject for Art and Manufacture under the Medieval Trade Guilds.

MICHIGAN

New Officers.—At the annual meeting of the Wayne County Medical Society held in Detroit, George E. McKean was elected president; Dr. Raymond C. Andries, vice president; Dr. James H. Dempster, secretary, and Dr. William H. Morley, treasurer, all of Detroit.

Government Selects Detroit Sanatorium.—The Detroit Tuberculosis Sanatorium has been selected by the United States Public Health Service as the institution for the treatment of Michigan soldiers and sailors who are suffering from tuberculosis. The institution is at present located at

Twelfth Street and Tuxedo Avenue and has accommodation for 150 patients.

New Sanatorium Superintendent.—Dr. Albert H. Garvin, for fourteen years superintendent of the New York State Sanatorium for Incipient Tuberculosis, Ray Brook, and who served for two years during the war on the Red Cross Commission sent to France, has been appointed superintendent of the new municipal tuberculosis sanatorium, which the Detroit Department of Health is constructing at a cost of \$1,000,000 on a site of 750 acres located near the village of Northville, 25 miles west of Detroit.

NEW MEXICO

Health Offices Moved.—The offices of the New Mexico Public Health Association, formerly located in the Chamber of Commerce Building, Albuquerque, have been moved to the Wright Building, in the same city. The office will be in charge of the new secretary, Clinton B. Anderson.

Personal.—James P. Keimedy, medical missionary of the Presbyterian board, and in charge of the Presbyterian Navajo Mission Hospital for eleven years, has severed his connection with that work and will enter private practice in New Mexico or Colorado.

NEW YORK

Medical School to Continue.—The Fordham University School of Medicine is to be continued during the next two years in order that medical students previously enrolled in this school may complete their medical training and obtain their degrees. During 1919-1920 subjects included in the junior and senior years will be taught, but during 1920-1921 only the subjects of the senior year will be given.

Educational Campaign in Housing and Industry.—The state reconstruction commission is undertaking an educational propaganda, through the use of motion pictures, by means of which various matters pertaining to housing, health and industry will be explained in picture form. The pictures will be exhibited free in parks and public squares in every section of the state within the next two months and will deal with such problems as the food question, the control of the milk supply, public health, housing, and the development of transportation in rural communities.

Postgraduate Course for Public Health Nurses.—A postgraduate course for public health nursing is to be given in Buffalo for sixteen weeks, beginning September 29, under the auspices of the Buffalo University, Buffalo Chapter of the American Red Cross, department of health, District Nursing Association and department of hospitals and dispensaries. The classes will be limited to thirty and applicants must be registered in New York state or states having equivalent standard. Applications should be made to the University of Buffalo. The expense of the course will be \$25.

New York City

Leprosy.—A man, 23 years of age, was found in Manhattan, August 22, suffering with leprosy. He came to the United States from Porto Rico, nine months ago, had first resided in Georgia, and for the last six weeks in New York City.

Men Arrested and Drugs Seized.—Internal Revenue agents, September 4, arrested five men said to belong to a "dope ring," and seized granulated opium and cocaine, valued at \$50,000. The prisoners were charged with violating the Harrison Narcotic Law and two of them were held in \$20,000 bail, another for \$7,500 and two for \$2,500. The latter two furnished security and were released, while the others were committed pending hearing.

Faculty Changes.—The following faculty changes in the Long Island College Hospital, Brooklyn, are announced: Dr. Emil Goetsch, full-time professor of surgery in Johns Hopkins University, Baltimore, and associate surgeon in Johns Hopkins Hospital, has been appointed professor of surgery at the Long Island College Hospital and head of the surgical department throughout the college, hospital and dispensary. Drs. William B. Brinsmade, William F. Campbell, both of Brooklyn, have been appointed clinical professors of surgery in Long Island College Hospital.

NORTH CAROLINA

Hospital Notes.—A charter has been issued to the Caroline General Hospital, Wilson, with an authorized capital of \$50,000. The incorporators are Drs. Kinchin C. Moore, Henry E. Best, Paul P. Lane and Ernest L. Strickland, all of

Wilson. The Bennett Barnes residence has been purchased and on this site will be erected a four-story building which will accommodate forty patients.

Personal.—Dr. Frank M. Register, for the past two years whole-time county health officer of Northampton County, and for fourteen years previously physician in chief to the North Carolina State Farm Prison, has been appointed state epidemiologist, and assumed the duties of the office at Raleigh, September 1.—Dr. Aubrey McR. Crouch, late state epidemiologist, becomes health officer of New Hanover County with headquarters at Wilmington.

Whole-Time Health Officers.—North Carolina now has fourteen whole-time county health officers, the three recent additions being Halifax, Robeson and Surry counties, which have voted appropriations sufficient to secure the cooperative financial assistance of the state board appropriations. Dr. Willur A. McPhaul, Lumberton, recently doing admirable public health work in Robeson County, leaves for work with the Alabama State Board of Health, his place being filled by Dr. Eugene R. Hardin, Clinton, late health officer of Sampson County. Dr. Paul C. Carter of Wake County assumes the duties of the post in Halifax, while the new health officer of Surry County is to be Dr. Lester L. Williams, who for the past year has been engaged in inspection work for the state board of health.

OHIO

Violation of Narcotic Law.—For the second time Dr. John B. Flack, Cincinnati, is said to have been put under arrest on the charge of violating the Harrison Narcotic Law. He is reported to have pleaded guilty and to have been released on a bond of \$1,000.

Personal.—Atlee R. Omstead, Major, M. C., U. S. Army, Millersburg, who spent twenty months overseas in the Medical Corps of the British Expeditionary Forces in France and Belgium, has returned and has located in Canton.—Dr. Frank W. Stevenson has succeeded Dr. Lauren N. Lindenberg as receiving physician of the Cincinnati General Hospital.

OREGON

Clinic Organized.—The Baker Clinic was incorporated, August 2, with a capital stock of \$50,000 and with the expressed purpose of conducting a general medical practice and surgery. The headquarters of the clinic will be in Baker, and Drs. Clarence E. Barton, Carl G. Patterson and Mr. James H. Nichols are the incorporators.

Personal.—Dr. Spiro F. Sargentich, Portland, who started for Serbia four days after war was declared and for more than two years conducted a campaign against typhus fever and later served two years and a half with the American Expeditionary Forces, has returned to his home.—Earl V. Morrow, Lieut.-Col., M. C., U. S. Army, Portland, returned home, August 4, after four years of service, the earlier part of which he spent as chief surgeon of the American Red Cross in Belgium, afterward he was attached to the Twenty-Ninth British Division and later was commanding officer of the 105th Sanitary Train, A. E. F., and finally chief surgeon of the Third Division.

PENNSYLVANIA

Personal.—Dr. William Estes, South Bethlehem, has been appointed by the state commissioner of health, chief of the genito-urinary dispensary at South Bethlehem.

County Court Powerless.—In the mandamus suit brought by Dr. John C. Bateson, Scranton, against the Bureau of Medical Education and Licensure, of the department of education, for reinstatement as a practitioner after his license had been revoked, the attorney-general has filed an answer to the effect that the Dauphin County Court has no jurisdiction in the matter.

Medical Inspection in Hazelton Schools.—For the first time in the history of Hazelton the city schools which opened for the current term, September 4, with more than 6,000 pupils have the services of a nurse. Hazelton physicians will attend to the medical inspection gratis, each doctor looking after the children of his own practice. The only condition the physicians exacted of the school board was that a nurse be supplied, so Miss Sue Tinner, a returned Red Cross hospital worker, was recently appointed to this post.

Philadelphia

Personal.—Dr. Edwin S. Cooke has been appointed by the state department of health, first assistant of the state genito-

urinary dispensary.—Dr. Melvin M. Franklin has been made associate professor of orthopedic surgery in the graduate school of the University of Pennsylvania.

Municipal Hospital Planned for Byberry.—Members of hospital and welfare organizations of the city are planning an educational campaign to arouse public opinion in favor of establishing a municipal tuberculosis hospital on the Byberry farms. Representatives from the bureau of public health and charities, the medical department of the municipal court, home service department of Red Cross, Pennsylvania Society for the Study and Prevention of Tuberculosis, federal board of vocational training, society for organizing charity, Phipps Institute of the University of Pennsylvania, tuberculosis department, Jefferson Hospital, and the state department of health, division of dispensaries, met, September 5, at the state dispensary, 1724 Cherry Street, to discuss plans for furthering the movement.

Joint Management for Women's College and Hospital.—Members of the executive boards of the Women's Medical College and the Women's Hospital, independent institutions, plan a joint meeting to decide on a method for the operation of the two institutions under a joint management. Dr. Alice M. Seabrook, medical superintendent of the hospital, said a union or merger of the two institutions is considered impossible by the officials of both, for although founded by graduates of the medical school, many hospital endowments specify that only women patients shall be admitted, whereas the hospital connected with the college receives patients of both sexes. Another factor in keeping the Women's Hospital and College Hospital separate is that while visiting physicians of the Women's Hospital are all women, physicians of both sexes are on the faculty and staff of the Women's Medical College and the College Hospital.

RHODE ISLAND

Licenses Revoked.—An official report states that at its regular meeting, held August 14, the Rhode Island State Board of Health revoked the licenses of Dr. Albert O. Robbins, Thornton, and Dr. Charles Dansereau, Woonsocket, on the ground that they had recently been convicted of performing criminal abortions.—At a meeting, held July 17, the state board of health of Rhode Island revoked the license of Dr. William Llewellyn Owen on the ground that he was found guilty of violating the Harrison Narcotic Law in the state of New York and was convicted by federal authorities. Dr. Owen's licenses to practice medicine have already been revoked in New York, Pennsylvania, California and Illinois. Dr. Owen was sentenced to serve a term at the federal penitentiary at Atlanta, Ga.

CANADA

Hospital Notes.—The Ontario Military Hospital at Orpington, Kent, England, closed this week and the last 400 patients sailed for Canada. The hospital buildings will probably be sold to the British pension authorities as a home for disabled pensioners; or the London County Council may purchase it as a home for city children in need of fresh-air treatment.

GENERAL

Army Pharmacists Organize. A World War Veterans Section of the American Pharmaceutical Association was organized at the annual meeting of that association, August 26.

National Colored Medical Society Meeting.—The twenty-first annual meeting of the National Medical Association, an organization of negro physicians, dentists and pharmacists, was held in Newark, N. J., August 26 to 29. Atlanta, Ga., was selected as the next place of meeting, and Dr. John P. Turner, Philadelphia, was elected president.

Bequests and Donations.—The following bequests and donations have recently been announced:

Mount Sinai Hospital, Charity Organization Society, St. John's Hall, and Hebrew Orphan Asylum, New York City, each \$1,000 by the will of Emile Roth.

Training School for Feeble-Minded Children, Elyria, Pa., \$10,000 by the will of John E. Parsons.

A bequest for the maintenance of three beds in the Methodist and Pennsylvania hospitals, Philadelphia, by the will of John B. Parsons.

Lenox Hill Hospital, New York City, \$5,000 by the will of Mrs. Anna Diehl.

Railway Surgeons to Meet.—The twenty-eighth annual session of the New York and New England Association of Railway Surgeons will be held at the Hotel McAlpin, New York City, October 20, under the presidency of Dr. James S. Hill, Bellows Falls, Vt. A symposium on "The Modern

"Treatment of Infected Wounds" will be presented and railway surgeons, attorneys, officials and physicians are invited to be present.

New Tri-State District Officers.—At the annual meeting of the Tri-State District Medical Society of Illinois, Iowa and Wisconsin, held in Rockford, Ill., September 1 to 4, the following officers were elected: president, Dr. Walter B. Helm, Rockford, Ill.; vice presidents, Drs. Elmer B. Cooley, Danville, for Illinois, George V. L. Brown, Milwaukee, for Wisconsin, and John E. O'Keefe, Waterloo, for Iowa, and business manager, Dr. William B. Peck, Freeport, Ill. Waterloo, Iowa, was selected as the next place of meeting.

The Osler Memorial Volume.—A number of inquiries have been received relative to the Osler Memorial Volume. We are informed that while the original intention was a one-volume book of 500 or 600 pages, so many contributions were received that the committee found it necessary to make two volumes, increasing the number of pages to between 1,300 and 1,400. This necessitated more time for publication. It is expected now that the volumes will be ready for distribution about the end of this month. Those who desire these books and who have not yet ordered may send their subscriptions to Dr. Henry Barton Jacobs, 11 Mount Vernon Place, Baltimore.—In explanation of the presentation to Osler on his birthday, July 12, it might be stated that a dummy volume containing such articles as were already in print was used in the presentation ceremony.

Meeting of Safety Congress.—An entire general session and two sectional meetings of the eighth annual Safety Congress of the National Safety Council will be held in Cleveland, October 1 to 4, and ample opportunity will be offered for the discussion of health service in connection with organized accident prevention work. Among the subjects to be taken up in the health service section are: industrial health hazards; the subnormal worker (pathologic); industrial dermatoses, bad teeth and fatigue; the scope of physical examination in industry; the industrial clinic; health education in industry; the coordination of industrial and community health activities; malingering, involving the problem of getting the sick or injured employee back to work; the treatment of burns, and what the war has taught us in surgery. The headquarters of the congress will be at the Hotel Statler.

Southwestern Tuberculosis Conference.—The Southwestern Tuberculosis Conference will be held at the Hotel Virginia, Long Beach, Calif., October 1 to 3, under the auspices of the National Tuberculosis Association. This conference includes the states of Arizona, California, Colorado, Kansas, New Mexico, Oklahoma and Texas, and the purpose of the meeting is to afford the opportunity for an exchange of ideas regarding the various public health and tuberculosis problems encountered in these states and the best way to meet them. The officers of the conference are: president, Dr. Robert A. Peers, Colfax, Calif.; vice presidents, Dr. Jeremiah H. Metzger, Tucson, Ariz.; Dr. Charles C. Browning, Los Angeles; Dr. Gerald B. Webb, Colorado Springs, Colo.; Dr. Samuel J. Crumline, Topeka, Kan.; Mrs. A. Otero-Warren, Santa Fe, N. M.; Mr. E. K. Gaylord, Oklahoma City, and Mr. J. D. Harper, Dallas, Texas, and secretary, Mrs. E. L. M. Tate-Thompson, Fresno, Calif.

Mississippi Valley Conference on Tuberculosis.—The Mississippi Valley Conference on Tuberculosis will be held at Des Moines, Iowa, September 22 to 24, with headquarters at the Fort Des Moines Hotel. In addition to the clinical programs, and schedules for September 23 and 24, a series of six demonstrations and clinics in early diagnosis of tuberculosis will be given under the auspices of the Iowa Trudeau Society. Leading clinicians from the northern states of the Mississippi Valley will be assisted by Dr. H. R. Landis of the Henry Phipps Institute, who is the representative at the conference of the National Tuberculosis Association. On the last day of the meeting one of the sessions will be devoted to the consideration of a plan for closer coordination of private and public health agencies to be presented by Dr. George Thomas Palmer, assistant director of the Illinois State Department of Health, Springfield, Ill. The luncheon round table will be presided over by Dr. William De Kleine, health officer of Flint, Mich., at which the field of the health officer in the campaign against tuberculosis will be considered.

FOREIGN

Red Cross Aid Against Tuberculosis in France.—Through the agencies of the American Red Cross, the campaign initiated by the French to combat the spread of tuberculosis

and which was practically nullified by the war, has been reopened and at present there is a capacity for 1,983 bed patients in hospitals in Paris and for 5,610 bed patients outside of Paris. The total number of beds established by the Red Cross Bureau of Tuberculosis amounted to 24,185. Aid was furnished to the extent of 3,287,417 francs and relief was supplied to the extent of more than three fourths of a million of francs.

Maternal Welfare Work in France.—Maternal welfare work, established in France under the auspices of the American Red Cross, children's bureau, by Dr. Fred L. Adair, Minneapolis, is to continue. A plan of prenatal consultation established by him is also to be continued. In the work in two sections in Paris, about 500 prospective mothers were cared for in the consultations, and also in their homes, and in the hospital social service work, which had been conducted only two months, more than 500 prospective mothers were interviewed and advised how best to meet their new problems of living. An organization has been formed to carry on the medical and social work installed in the hospital. An attempt is being made to form a society of social visitors who will be capable of teaching prospective mothers the proper methods of caring for themselves and of making preparations for childbirth.

Meeting of Swedish Medical League.—For the first time since the beginning of the war, the *Almänna svenska Läkaresällskapet* held a representative meeting in August and outlined new plans for safeguarding the economic and other material interests of the profession. The league invited members of similar organizations in Denmark and Norway to consult with them in regard to enlarging the scope of the organization. Its efficacy has been hampered in the past by the fact that some 400 physicians in Sweden have not cared to join the league, so it does not represent the entire profession, while in Denmark and Norway, nearly every member of the profession is enrolled in their respective organizations. The Swedish profession has not felt the need for organization so much in the past, but now vital questions in regard to sickness insurance, etc., are confronting them and vigorous efforts are being made to rouse physicians throughout the land to organize for more effectual action. The corresponding Norwegian society has a board of various officers, but the management is placed in the hands of the general secretary, Dr. R. Hansson, who gives his entire time to the work, with an annual salary of 20,000 crowns. He is empowered to consult with other members of the board residing in Christiania, as the chief officers live elsewhere. The Swedish league has a by-law to the effect that the president must be a resident of Stockholm, the headquarters of the society. It publishes a special journal, the *Almänna svenska Läkaresällskapet*. The president of the league, Professor Lennmalm, has been appointed rector of the Karolinska Institute and on his resignation, Prof. H. Forssner was appointed president. The name of the league was changed to *Sveriges Läkaresällskapet*. The *Tyckskrift för Lager*, which is the organ of the corresponding Danish league, comments that the meeting will undoubtedly make its influence felt in closer relations between Scandinavian medical men in general.

LATIN AMERICA

Prize for Ambidexterity.—The Asociación Escuela de Medicina of Guayaquil, Ecuador, has offered a prize of \$100 for the teacher who can present at a public meeting, May 5, 1920, the largest number of scholars trained to use both hands for the ordinary demands of life and especially for handwriting. Competition is restricted to teachers of the province of Guayas.

Yellow Fever.—Major-Gen. William C. Gorgas, formerly Surgeon-General, U. S. Army, who has been investigating the sanitary matters in Central and South America, has, it is reported, offered to assume technical directorship of the sanitation of Guayaquil, Ecuador, provided the money for the work is supplied by the municipality or the republic. —At the request of the Peruvian authorities, General Gorgas is about to proceed to Pinar, about 210 miles from Guayaquil, which is infected with yellow fever. General Gorgas and his party left Guayaquil, Ecuador, for Callao, Peru, September 1.—Dr. M. E. Conner, chairman of the Rockefeller Foundation Commission to Guayaquil, Ecuador, was presented with a gold medal, August 11, in recognition of his services in the campaign against yellow fever.—New cases of yellow fever were reported, September 1, at Corinto, Nicaragua, and Amapala, Honduras.

LONDON LETTER

LONDON, Aug. 13, 1919.

Reconstruction at Guy's Hospital

With the conclusion of the war, reconstruction has been the keynote in much of our public life, and medical organizations are by no means exempt. A new departure at the London Hospital—the appointment of paid whole-time physicians who will devote themselves entirely to hospital work, including research—has been previously recorded in these columns (April 12, p. 1091). At Guy's Hospital a similar scheme is being inaugurated. A committee of the medical school has been for some time considering what changes are necessary to secure the better preparation of medical students for the practice of their profession, a more effective use and coordination of medical skill for the benefit of patients under treatment in the hospital, and constant advances in medical science. The recommendations of the committee have been approved by a meeting of all the teachers in the school, and will come into force next October. Owing to a rebuilding scheme, which has been held up by the war, the hospital is short of beds. As soon as more become available, it is intended to appoint a professor of clinical medicine; and possibly a similar innovation will take place on the surgical side. But it is thought to be a mistake to await this appointment before initiating a new kind of advanced teaching. Accordingly, Dr. Hurst, the present head of the neurologic department, will be given the title of "director of advanced studies in clinical medicine." Beside taking on the duties of full physician, he will still remain head of the neurologic department, but an assistant neurologist will also be appointed. His beds will form a mediconeurologic clinic, half of them being devoted to neurology and half to general medicine. The assistant neurologist and an assistant physician will work with him, each of them taking charge of a quarter of the beds in the clinic. Dr. Hurst looking after the remaining half. Once a week Dr. Hurst and the assistant physician will examine all their medical patients together, and once a week Dr. Hurst and the assistant neurologist will examine their neurologic patients together. There will be clinical demonstrations and lectures on four mornings in the week for six months during the winter from 12 to 1, and on one of these mornings there will be a combined demonstration with the corresponding surgeon or with one of the heads of the special departments. There will be ample opportunity for graduates and others who wish to take up some special line of medical investigation.

There will also be important changes in the other medical and surgical "firms." At present the assistant physicians and assistant surgeons act rather as locum tenentes to the physicians and surgeons than as assistants. The "unit system" which is to be adopted implies the linking together of the two in one firm, each firm having its own beds and its own outpatient department. The head of the unit and his assistant will be associated in teaching and in investigating cases. On the medical side it is hoped that once a week there will be a combined round, when cases of special interest will be discussed. The surgeon and assistant surgeon will operate on the same afternoons, preferably in adjacent theaters, and in special operations they may be able to render each other assistance. The assistant physicians and assistant surgeons will take charge of a quarter of the beds of the unit. There will be a registrar, house officer, clerks and dressers attached to each medical and surgical unit. Closer linking of the wards and laboratories will be brought about by arranging that members of the junior staff shall usually hold two appointments. There will be four medical registrars and four surgical registrars, one attached to each firm. These will be part-time appointments. The registrars will be able to hold demonstratorships in the departments of the medical school, as the anatomic, physiologic, pathologic or bacteriologic departments, or they may hold clinical assistantships in the various special departments. The association of the wards and laboratories will be further facilitated by the creation of eight new part-time posts. The holders of these posts will be called medical or surgical assistants. There will be one attached to each firm. They will have no routine duties in the wards, but they will spend their time carrying out medical or surgical investigations under the supervision of the head of the firm and the head of one of the laboratories. The assistants, like the registrars, may hold other part-time appointments in the hospital or medical school. Further, these new appointments will be open to men from other schools. Graduates who come to Guy's for shorter periods of study, and wish to carry out clinical investiga-

tions, will likewise be given the title of "assistant" (unpaid) so as to obtain a status in the wards. When all these posts are filled, there will be, besides the mediconeurologic clinic, three medical firms and four surgical firms, each firm consisting of two members of the staff, a registrar and assistant house officer, and a number of clerks or dressers. The present assistant surgeon's firm will no longer exist as a separate entity. Each firm will be complete in itself, carrying on its own outpatient department in close association with its inpatient department.

Gas Poisoning: A Question of Survivorship

A curious case has been raised in the probate court as to the survivorship of a husband or wife who died of poisoning by illuminating gas. They were both over 80 years of age, lived alone, and were found dead in their bedroom one morning. As the husband had left in his will all his property to his wife, the question of survivorship had to be settled between her executrix and the husband's next of kin. On the day before death she complained that the gas fire in the bedroom kept "popping" and wanted cleaning. The husband was found lying on the floor in front of the gas fire from which gas was escaping. He was partially dressed. Nearly was a pair of pliers. The wife lay on the bed on the side farthest from the gas fire, and on the table by the bedside was a novel and a small paraffin lamp, still burning. The burden of proving that the wife survived lay on her executrix. It was submitted that as the husband was on the floor nearest to the escaping gas, the wife survived. The judge held that there was no evidence that the wife survived, and therefore decided in favor of the husband's next of kin.

Wood Alcohol as a Beverage

No cases of blindness due to methyl alcohol, such as have been described in the United States by Casey Wood and others, have been observed in this country. This has been explained by the fact that methyl alcohol in a refined form, such as Columbia spirits, is not produced here, the methylate spirit produced for commercial use being too nauseous for drinking. However, cases of drinking them are reported from time to time. The Dundee Town Council has recently approached the government with regard to the growing use of wood alcohol as a beverage, and with the proposal that it should be rendered still more nauseous by the addition of chemicals which would make it entirely unfit for human consumption. The experience of Dundee is corroborated by practically every city in Scotland. The increased consumption is probably due to the scarcity of whisky following the war.

Dentistry in the Army

In his presidential address at the annual meeting of the British Dental Association, held in London, Mr. Montagu F. Hopson delivered a scathing indictment of the military authorities. He said that the outbreak of the great war found our forces quite unprepared dentally. There was no organized dental unit, either for home or for field purposes. All the resources of the association were at once placed at the disposal of the government, but expert advice was rejected. Service dental arrangements were mismanaged, not to say bungled. Failure to grasp the situation may have been due to ignorance on the part of the chiefs of the army medical department to begin with, but they later displayed a culpable obstinacy which led to a grave wastage of man power and a large amount of unnecessary and easily preventable disease and suffering among the troops in the field and the wounded in our hospitals. The policy of the executive was clear and definite, and was finally vindicated, namely, that with an acknowledged general shortage of dentists, even to meet the needs of the civil population, they could most advantageously serve their country in the national emergency in their professional capacity, and that all should be mobilized for service. This obvious fact was only slowly recognized. Dentists commissioned as temporary lieutenants on the general list were appointed in dribbles and were employed under the supervision of medical officers possessing no dental knowledge. There was an utter lack of organization. Examples of efficiency furnished by our colonial forces were persistently ignored. In the meanwhile, skilled and highly trained men were being wasted in the ranks, the preferred services of those possessing expert knowledge in the treatment of facial injuries were declined, and dental schools, the nurseries of professional recruits, were depleted. For three whole years the government remained indifferent to the value and importance of the dental surgeon as a national asset. As the war drew to its victorious close some sort of order

gradually evolved in army dental arrangements, but there was still lacking that one essential to an efficient organization—an administrator, possessing a dental qualification, and given unhampered authority over the men under his command. Mr. Hopson held that while army dental treatment must be closely linked with the Royal Army Medical Corps, it can never be adequate until a definite dental corps has been established, modeled on the lines adopted by our colonies and certain of our allies. Similar corps must be formed for the navy and the air force.

PARIS LETTER

PARIS, Aug. 14, 1919.

The Treatment in Pott's Disease

At a recent meeting of the Société de chirurgie de Paris, Dr. Théodore Tuffier communicated the results of his attempts to treat Pott's disease by the Albee method. Since 1911 Tuffier has applied this method to eleven patients with Pott's disease, aged from 17 to 59, who had been suffering from the disease for from four months to five years, and who presented a kyphosis involving a variable number of dorsolumbar vertebrae and complicated at times by a cold abscess. The favorable prognosis of this operation is remarkable. On one occasion, the graft broke; nevertheless, the anatomic and therapeutic results were perfect. In another case, the graft was expelled owing to suppuration. In spite of this fact, a solid mass of bone was formed which welded together the spinous processes and immobilized perfectly the spinal column.

As for the more remote therapeutic results, the history of five cases was followed for from one to three years after the operation. Three of these patients are in a very satisfactory condition, both generally and locally. They complain little or not at all of fatigue or pain, and present an absolute immobility of the region operated on. The fifth patient, although immobilized in the region operated on, presented a new focus in the upper portion of the dorsal cord. One patient could be seen only once after the operation; namely, two months later. She was at this time in perfect condition; walked without fatigue and had no pains. Another patient succumbed to pulmonary tuberculosis and to multiple osseous suppurations. Necropsy revealed that the union between the graft and the spinous processes was absolutely perfect and that the spinal column was completely immobilized.

Tuffier also reported that he had recently (in March, 1919) applied with success the Albee method to the treatment of a patient with suboccipital Pott's disease, but that he had varied the technic slightly in that he had immobilized the cervical vertebrae for several days after the operation by means of a Minerva cast. A recent roentgenogram shows the graft in place and the two extremities definitely fixed. The head is immobilized, and only the neck executes the necessary movements of flexion and extension.

The Nineteenth Congress of Urology

The nineteenth congress of the Association française d'urologie will open in Paris at the Faculté de médecine, Oct. 8, 1919. The main question to be discussed at the congress is: traitement des pyélonéphrites non-tuberculeuses chez l'homme (the treatment of nontuberculous pyélonephritis in man).

The Use of Mineral Springs for Soldiers

Dr. Louis Mourier, undersecretary of state for the army medical department, has decided to increase considerably the number of mineral springs at which soldiers (whether in active service or discharged) whose affections, contracted or aggravated by military service, are amenable to thermal treatment may be cared for. Before the war there were only six military hospitals located at thermal springs. These were at Amélie-les-Bains, Bourdon-Fontaine, Bourlomme, Plombières and Vichy. During the war, profiting by the fact that most of the thermal springs had transformed their hotels into temporary hospitals, the army medical department instituted thermal treatment for soldiers in thirty-six of the spas. During 1918, about 20,000 men received treatment. After the war closed it of course became necessary to turn the hotels back to their civilian clientele.

A commission was appointed to decide on a list of springs that seemed necessary in order to meet the needs of at least the majority of medical and surgical cases among the soldiers, both active and discharged, in which indications were such as to make thermal treatment advisable. A recent circular enumerates the twenty stations designated by the

commission, and states the necessary formalities that must be complied with in order to secure admission to the stations for treatment. The main requirement is the filling out of a blank setting forth the principal indications for such treatment.

Interallied Conference Relative to the War Mutilated

The third interallied conference for study of questions relative to the war mutilated will be held at Rome, Oct. 12-17, 1919, under the chairmanship of Prof. Riccardo Galeazzi.

An Expression of Gratitude

Marshal Pétain, commander of the armies of the north and northeast, recently addressed an open letter to M. Jean Dupuy, president of the Syndicat de la presse parisienne, in which he expressed gratitude in the name of the French army for the Oeuvre des trains de blessés, a soldiers' welfare society organized by the syndicate. From the beginning of the war this society, which was particularly well organized, devoted itself most actively and generously to the various medical services. Under the most difficult circumstances the personnel of the society gave of their time, money and strength without counting the cost.

The French Red Cross in Lithuania

Mme. Edgar Wisner, a volunteer nurse of the Association des dames françaises (one of the three societies that go to make up the French Red Cross), has offered her services for the organization and direction of a relief expedition to be sent to Lithuania. The sending of this expedition was decided on after the receipt of appeals for assistance from Lithuania, which was completely devastated by the Germans. With the aid of the undersecretary of state for the army medical department, Mme. Wisner is in a position to carry out the project. A stock of provisions, clothing, surgical dressings, etc., has been secured through contributions from the French Red Cross, as well as other war welfare organizations working under the auspices of the undersecretary of state for the army medical department. Mme. Wisner, who has already left France for Lithuania, is assisted by Mlle. Nine Decourtray, also a volunteer nurse.

Death of Dr. Félix Brémont

Dr. Félix Brémont, honorary president of the Syndicat de la presse scientifique, died recently at Lavandou (department of the Var) at the age of 76. Dr. Brémont is the author of several medical works, among which may be mentioned "Les préjugés en médecine" and "Rabelais médecin."

Restrictions Regarding the Use of Thermal Springs

Are bathers at thermal springs under obligations, before commencing treatment, to provide themselves with a circular of instructions issued by the attending physician of the thermal station, as asserted by the superintendent of the thermal establishment of Saint-Christau (department of Basses-Pyrénées)? A court decision has been rendered in the negative which upholds the principle of absolute liberty as regarding the use of thermal and mineral springs, since no administrative regulations have been issued restricting the application of the law of 1860.

The Action of Centrifugal Force on the Human Organism

At a recent meeting of the Academy of Medicine, Professor Broca and Dr. Garsaux gave a report of some experimental studies made on animals subjected to centrifugal force. These studies were carried out with a view of ascertaining the causes of the accident which recently befell the aviator Gilbert. An aviator is supposed to be able to resist twenty times his own weight. At this pressure, there are elements of danger for the human organism. Broca and Garsaux put animals weighing from 10 to 13 kg. in an especially constructed centrifuge. The movements of the centrifuge produced signs of undue pressure on the nerves accompanied by cortical epilepsy and lesions of the cerebellar peduncles. The animals were subjected for the space of five minutes to a force varying from twenty-five to ninety-eight times the force corresponding to their weight. At the last trial of high speed, at the extreme limit, they brought about the quick death of the animal. The animal had resisted a force up to eighty times its own weight. In the trials that terminated in the death of the animal the abdomen was found to be gorged with blood.

From these experiments Broca and Garsaux concluded that, though the violent destruction of the organism is not a cause for anxiety, nevertheless the centrifugal force may give rise to disturbances of the circulation and to lesions of the nerve centers within the brain.

Marriages

LAWRENCE CHESLEY CHISHOLM, Asst. Surg., Lieut. (j. g.), U. S. Navy, Salem, Mass., to Miss Olive R. Conrad of Hagerstown, Md., August 21.

JOHN HADLEY CALDWELL, Newport, Ky., to Dr. Ida MAY WESTLAKE of Cincinnati, at Mount Vernon, Ohio, August 20.

EDWARD PETER HELLER, Capt., M. C., U. S. Army, Philadelphia, to Miss Naomi Williams of Catsauna, Pa., August 27.

THOMAS JUDSON MCBEE, Morgantown, W. Va., to Miss Norma Mildred Wright of Keyser, W. Va., August 14.

THOMAS BARRETTE BOLAND, Chicago, to Miss Ethel Johnson, at Milwaukee, August 20.

RAYMOND WILLIAM PAUL to Miss Emily E. Shield, both of Richmond, Va., August 6.

JEREMIAH A. O'CONNOR to Miss Katherine Spoori, both of Chicago, August 30.

Deaths

Joseph Pogue, Edwardsville, Ill.: Pennsylvania Medical College, Philadelphia, 1852; aged 84; who served throughout the Civil War, first as surgeon in chief of Burgess' Sharpshooters with the rank of major, and later as chief of the operating board; one of the organizers of the Madison County Medical Society, its secretary in 1857; and one of the chief promoters on the occasion of its reorganization in 1903; a surgeon of marked ability; died at his home, August 19, from pneumonia.

Charles Campbell Kimball * Watertown, N. Y.: University of Buffalo, N. Y., 1895; aged 57; for the last four years commissioner of the board of health of Watertown; oculist and aurist to St. Joachim's Hospital and the New York Central system; a specialist on diseases of the eye, ear, nose and throat; died at his home, August 16, from nephritis.

Christian Sihler, Cleveland: University of Michigan, Ann Arbor, 1871; aged 70; formerly professor of histology in the Western Reserve University, Cleveland; one of the founders of Lutheran Hospital, Cleveland, and president of the medical staff until 1910; medical director of the Windsor Hydratic Institute; died at his home, August 22.

Wilbur Pledge Stubbs * Baltimore: University of Maryland, Baltimore, 1902; aged 39; school examiner for the Baltimore Health Department; a specialist in pulmonary diseases; a member of the staff of the University Hospital, Baltimore; died in that institution, August 25, from disease of the kidney.

Commodore Perry Coulson, Chelsea, Iowa: State University of Iowa, Iowa City, 1889; aged 58; a member of the Iowa State Medical Society; for one term mayor and health officer of Chelsea, and for several years a member of local school board; died at his home, August 15, from diabetes.

Herbert Granville Leslie * Amesbury, Mass.: Harvard University Medical School, 1899; aged 48; a specialist on diseases of the ear, nose and throat; died at the Anna Jaques Hospital, Newburyport, Mass., September 1, from peritonitis following an operation for appendicitis.

Thomas R. Hillard, Widnoon, Pa.: University of Illinois, Chicago, 1899; aged 50; who served as captain, M. C., U. S. Army, for two years, was discharged, March 8, 1919, and located in Oak Mount, Pa.; died in that place, June 18, after an operation for appendicitis.

Albert Lane Norris, Cambridge, Mass.: Harvard University Medical School, 1865; aged 80; a member of the Massachusetts Medical Society; assistant surgeon of U. S. Volunteers during the Civil War; died in the Deaconess Hospital, Brookline, Mass., August 29.

John R. Boynton, Chicago: Hahnemann Medical College, Philadelphia, 1880; formerly president of and professor of surgery and clinical surgery in Hering Medical College, Chicago; died in the Wabash Valley Sanitarium, Laayette, Ind., August 22.

William H. Hubbard, Marion, Ind.: Medical College of Indiana, Indianapolis, 1878; aged 70; from 1879 to 1883 a member of the staff of the Central Indiana Hospital for the Insane, Marion; died at his home, August 23, from cerebral hemorrhage.

Francis Reber Musser * Oakland, Calif.: University of Pennsylvania, Philadelphia, 1895; aged 59; a member of the Pacific Coast Oto-Ophthalmological Society; a specialist on diseases of the eye, ear, nose and throat; died at his home, August 26.

Robert Laughlin, Steubenville, Ohio: Western Reserve University, Cleveland, 1876; aged 67; a member of the Ohio State Medical Association; a member of the local board of education; died at his home, August 23, from cerebral hemorrhage.

Zebulon Hamilton Shultz * Masonville, Ky.: Hospital College of Medicine, Louisville, Ky., 1901; aged 52; died at his home, July 14, from the effects of carbolic acid, self-administered, it is believed, with suicidal intent.

Edward Ratch Sisson, New Bedford, Mass.: Berkshire Medical College, Pittsfield, Mass., 1853; Homeopathic Medical College of Pennsylvania, Philadelphia, 1854; aged 90; died at his home, August 27.

John J. Roberts * Scranton, Pa.: University of Vermont, Burlington, 1885; aged 59; at one time coroner of Lackawanna County; who was operated on, July 28, for intestinal obstruction; died, July 31.

James D. Graham, Dalton, Ga.: Atlanta (Ga.) Medical College, 1868; aged 84; surgeon in the Confederate Service throughout the Civil War; died in a hospital in Atlanta, August 14.

Joseph McCann, Columbus, Ohio: Columbus (Ohio) Medical College, 1879; aged 65; died in the Grant Hospital, Columbus, August 28, from the effects of a carbuncle of the neck.

H. W. A. Prichard, Harrisonburg, La.: Tulane University, New Orleans, 1899; aged 49; died in Natchez, Miss., August 11, from acute gangrenous appendicitis.

William M. Pierson, Morristown, Ind.: Medical College of Indiana, Indianapolis, 1874; aged 69; died at his home, August 16, from chronic interstitial nephritis.

Charles G. Anderson * Detroit: Detroit College of Medicine, 1893; aged 50; died in Harper Hospital, Detroit, August 19, from hemolytic jaundice.

Charles William Powell, Lowndeshoro, Ala.: University of Alabama, Mobile, 1890; aged 53; died at his home, August 6, from tuberculosis of the intestines.

Edward Womack Currie * Charlesbury, N. C.: North Carolina Medical College, Charlotte, 1907; aged 41; died at his home, June 26, from pneumonia.

Elmer Burton Hadley * Waterloo, Iowa: Eclectic Medical College of Indiana, Indianapolis, 1905; aged 49; died in Indianapolis, June 4, from uremia.

Horace Clinton Coolman, Hudson, Ohio: Cleveland University of Medicine and Surgery, 1869; aged 70; died at his home, August 15, from carcinoma.

Ralph Raum Boyle, Philadelphia: Jefferson Medical College, 1887; aged 52; died at his home, August 26, from congestion of the brain.

Joel L. Selman, Douglasville, Ga.: Atlanta (Ga.) Medical College, 1879; aged 64; died at his home, August 13, from heart disease.

George Hadden, Alta, Iowa: Minnesota Hospital College, Minneapolis, 1888; aged 75; died in Alta, June 24, from myocarditis.

George Lawrence McDermott, Denver: Rush Medical College, 1897; aged 48; died at his home, August 23, from heart disease.

Christiana A. Cook, San Francisco (license, California, 1876); aged 88; died at her home, August 20.

Louis P. Knoll, Newcastle, Pa.: Baltimore University, 1904; aged 42; died in Buffalo, August 12, from tuberculosis.

John Charles Kerr * Lieut., M. C., U. S. Army, Jefferson, Pa.: University of Pittsburgh, 1897; aged 48; died Oct. 27, 1918, from bronchopneumonia. In THE JOURNAL of March 8, the death of Dr. John Clem Kerr, Lieut., M. C., U. S. Army, Hazelwood, Pittsburgh, was announced. This was an error. The announcement should have read as above written.

* Indicates "Fellow" of the American Medical Association.

... He knows nothing of the effect of drugs and he is incompetent to prescribe their use. When he sells one form of treatment for all forms of rheumatism, irrespective of the superinducing cause or causes of the trouble, he well knows that it is mere guess-work on his part—a hit or miss chance of recovery, and when he calls such a treatment a 'Specific for Rheumatism,' and solemnly urges its use as a cure for practically all forms of rheumatism he knows that he is not acting in good faith, and his scheme for obtaining money through the mails by such means should be suppressed. This medically unlettered layman poses as an expert in the treatment of rheumatic conditions and has the boldness to display to the public at the head of one of his pamphlets the words, 'Rheumatism, Its Cause, Its Cure, by Jesse A. Case, F.S.Sc. (London).' The representations made by him throughout his entire literature are of a character which have frequently been declared fraudulent by this department. ... Case describes how he cured himself of a bad case of rheumatism, and this alleged fact was amplified by his direct testimony; but the cross-examination of him shows that he had other troubles, which when removed by treatment other than his own remedy, what he thought was rheumatism gave him no more trouble. The evidence strongly indicates that if he had rheumatism at all it was by no means a serious case. He did have some other serious trouble, as his testimony shows, all of which was treated by physicians and surgeons successfully, after which he regained his health. The postmaster at Brockton, Massachusetts, reports that Case is receiving an average of twenty-eight letters a day in the conduct of this business."

Correspondence

PATHOLOGY OF THE MOUTH IN SCURVY

To the Editor:—I am prompted to write because of the editorial on "Diet in Relation to the Teeth" (*THE JOURNAL*, Aug. 9, 1919, p. 425).

It is true that the dental profession has gone daft on the subject of bacteria as a cause of disease in the mouth. The statement that "they [dentists] seem not to realize that the presence of bacteria in itself never causes disease; we have millions of bacteria in our intestines and still thrive. What harm do the micro-organisms do in the mouth?" is timely. If the dentists were more broadly educated, much time could be saved in the present methods of research. The "powers of resistance" have as much to do with diseases in the mouth as in other parts of the body—indeed, more so in regard to scurvy and kindred diseases of the jaws and alveolar processes, which is my purpose here to show.

The editorial quotes Zilva and Wells (Changes in the Teeth of the Guinea-Pig. Produced by a Scurbetic Diet, *Proc. Roy. Soc.*, London, B 90:505, 1919), who have made extensive experiments in studying scorbutic animals at the Lister Institute in London. The following are the important points brought out:

In advanced cases of scurvy, in guinea-pigs and monkeys, the teeth were apparently sound, but useless, since they had been loosened by the gradual absorption of the cement membrane of the alveolar sockets, which had left exposed that position below the neck. As a result, Zilva and Wells state, there must have occurred that periosteal pain, or something analogous, which follows in the case of human patients who are suffering from shrunken alveoli. These teeth also presented, in addition, all the appearances of the changes of senility.

In a scurvy tooth, the condition persists right up to the apex of the root; the change appears to start first in the odontoblastic cells at the top of the pulp, working down toward the apex, followed by distended blood vessels and hemorrhage; then complete fibroid degeneration follows.

If we may believe the new evidence, which deserves a respectful hearing, the teeth are among the parts of the organism first affected by scorbutic causes. Damage may be detected in the teeth before any other symptoms are discovered. For this reason it is not at all unlikely that tooth defects arise owing to faulty diets that are not clearly recognized beforehand.

These points were all discussed and verified by me more than twenty-three years ago. They have all been reiterated over and over in reports of my researches in more than thirty papers, published in different medical and dental journals and in two books from 1886 up to the present time.

Constant research work has been conducted since 1878 on diseases of the alveolar process and teeth resulting from scurvy and lead poisoning, on dogs, cats, guinea-pigs, mice, sheep, cows, horses, monkeys and human material. Cases were obtained at the Cook County morgue and at the Cook County Insane Asylum at Dunning. Animals were salivated with mercury. Material from patients with tuberculosis, other wasting diseases, senility and autotoxic conditions were also examined. This work has all been illustrated, and the progress of the different diseases is comprehensively shown by photomicrographs and halitones.

To appreciate the pathology of the alveolar process, we must first have a clear idea of the anatomy and functioning of the jaws, alveolar process and teeth, since the structures here involved have no analogue in the human body. In some of the lower vertebrates there is a constant succession of teeth throughout life. One set is used for a short time, is shed, and a new set takes its place. As we rise in the scale of evolution, certain animals, including man, possess only two sets. The first is used for the purpose of masticating soft substances, and later when harder and more varied food is required, the first set is shed and a second takes its place which is intended to last as long as life.

When the animal or child is born there are no teeth and hence no alveolar process. While the teeth are developing, the bone or alveolar process builds itself about the teeth to hold them firmly in position. When these teeth are shed to make room for the second or permanent set, the alveolar process absorbs away. When the second set appears, the alveolar process builds itself about these teeth to give them greater strength than the first set. When the second teeth are extracted or lost by disease, the alveolar process again absorbs away. The alveolar process, therefore, is intended only to hold the teeth in position while they are in the jaw. It will be seen that the alveolar process is a transitory structure and is, therefore, very sensitive to a lowered vitality, irritation and disease.

The tooth, so far as disease of the alveolar process is concerned, is a foreign body. The only blood vessels which enter the tooth go direct from the main trunk into the apical foramina to make up and nourish the dental pulp. There are no blood vessels in normal tooth structure. The blood vessels in the alveolar process extend from the neck of the tooth to the end of the root, but reach only the cement of the tooth. The alveolar process, then, is an end-organ—dental pulp.

In disease, then, the tooth can be considered only as a foreign body. The alveolar process being a transitory structure and an end-organ, it is easy for the physician to understand why disease, including anemia, first attacks the alveolar process and why the alveolar process, and not the "teeth," is always first to indicate systemic disturbances.

For more than thirty years I have been able to detect systemic disturbances, such as anemia, kidney and heart lesions, metal and other poisonings, before they were recognized by the patient.

The simplest and most marked illustration of disease of the alveolar process is the symptom of senility. Absorption may begin as early as 30 years of age, and many persons lose all their teeth at 60. Absorption occurs in every mouth over 50 years of age. In my lectures to impress this important point on students I have often made the statement: If man lived long enough and remained in apparently good health, every one would lose his second teeth by absorption of the alveolar process. This might be called normal senile absorption. It is due to autotoxic and other poisons circulating in the blood.

The next most marked illustration of disease and poisons acting on the alveolar process is that of metal poisoning. Patients working in paints, in metal mines, in the arts, etc., frequently become ill. The first symptom of poisoning is developed in the alveolar process. All physicians are familiar with the old method of prescribing mercury, arsenic and other metallic drugs. The system was supposed to have received enough of the drug when "the gums are touched," meaning, of course, when they have become slightly inflamed. The character of the poisoning was indicated by the color of the

gums. In lead, the gums became blue; in brass, yellow; in mercury, red, etc. The metals accumulating in the tissues because of the end-organ nature of the structure gave the color to the gums, and also as an irritant caused inflammation.

Perhaps the most interesting symptom of bone absorption is that produced by anemia or some form of heart lesions in which the blood supply of the alveolar process is diminished. Nourishment is cut off and the alveolar process rapidly absorbs away without pain or pus. These people attend to their daily affairs and are not able enough to call a physician. The conditions referred to above are all called constitutional causes.

The local causes are all irritants, such as tartar, bad dentistry, excessive use of the tooth brush, tooth picks, etc. These irritants cause the blood to flow into the gums and alveolar process resulting in stasis. Nourishment is cut off and altered metabolism occurs, resulting in bone absorption.

The constitutional and local causes produce what I have called interstitial gingivitis (sometimes the irritation, inflammation and absorption begin at the apex or at another part of the root, but oftener at the gum margin, depending on the cause; hence the name). In their milder forms they have now been explained. There is no pain or soreness attached to this pathologic process. There is simply first absorption of lime salts, after which the fibrous tissue may remain, holding the loose tooth in position for an indefinite period, after which fibroid degeneration takes place and the tooth drops out.

If there is the least soreness, it does not occur until after the lime salts have been removed and the tooth has become loose.

The fibrous tissue may hold the tooth in position for years. The "cement membrane" (peridental), therefore, must be present for the attachment of these fibers to the tooth. The alveolar process, including the fibrous tissue, must first be destroyed, and not the "cement membrane," as stated in the editorial, after which the membrane disappears.

With these simple forms of pathologic conditions of the alveolar process explained, the action of the more severe forms of disease, such as scurvy, on the gums and alveolar process can be better understood.

The constitutional changes due to want of proper diet, altered metabolism, malnutrition, and want of resistance both in the system and in the alveolar process, together with stasis or impoverished blood, as well as poisons (irritants) in the blood, set up a violent inflammation with bone absorption and pain.

My researches do not admit of infection as a cause in any of the conditions cited. The infections, such as actinomycosis, Vincent's angina and trench mouth, which produce the same pathologic condition, are interesting but have no place in this communication.

EUGENE S. TALBOT, M.D., Chicago.

NEED OF GOVERNMENT ACTION TO CHECK BOTULISM

To the Editor:—I have just read with much interest your timely editorial on "The Relation of Forage Poisoning to Botulism" (*THE JOURNAL*, Aug. 23, 1919, p. 611), in which you refer to my recent contribution on this subject (*Am. J. Hyg.*, 158:37 [July] 1919). May I venture to make a few comments partly in emphasis of what you have said, and partly additional thereto, hoping thereby to accelerate a movement toward government action, which I deem absolutely essential to the protection of the public health?

You refer to the recovery of one desperately ill patient under the use of the serum furnished by Professor Graham of the University of Illinois. I wish to say that I have never seen a more direct and striking rescue of a patient from an apparently hopeless condition by a single therapeutic agent on clinical trial for the first time. I should like to call attention to one very instructive point in another case (Case VI), in which Dr. Smith observed bor-

hygisms as the first indication of recovery from the intestinal paralysis.

The neutralization of the botulinus toxin by fats cannot be too strongly emphasized, and clearly demands the prompt and energetic use of castor oil or some other laxative fat, for the double purpose of clearing out the ingested toxins, which are largely preformed under saprophytic conditions, and of lowering or destroying the virulence of the toxins by combination with fats. *This must be done quickly*, as intestinal paralysis rapidly supervenes, after which laxatives are, of course, entirely inert.

Another point which cannot be too strongly emphasized is that boiling not only kills the germ but also destroys the toxin. Thorough cooking is the most important prophylactic measure against this very widely distributed pathogenic saprophyte.

In this connection I am wondering whether economy of fuel in continental Europe, and the consequent less thorough cooking, which may of course be a matter of taste and habit as well, might not account for the apparently greater prevalence of botulinus outbreaks there. Their frequent and economically serious occurrence in this country among horses and other valuable animals is also suggestive, owing to the absence of cooking in ensilage food. Of course the latter, in the deeper layers of the silo, furnishes typical anaerobic conditions for the growth of this organism. So far as I know, animals are no more susceptible than man to this toxin.

I wish to urge that the machinery of the great American Medical Association be set in motion, in order that it may bring its influence to bear on the proper governmental departments, that there may be provided the greatest degree of protection both by way of prophylaxis and the prompt availability of a curative serum, the efficacy of which has been fully demonstrated experimentally on animals and to a very limited but apparently satisfactory degree on human subjects.

G. W. McCaskey, M.D., Fort Wayne, Ind.

"CONDUCTIVE ANESTHESIA BY INTRA- SACRAL INJECTION OF PROCAIN"

To the Editor:—In *THE JOURNAL*, July 26, 1919, p. 298, appeared an abstract of an article of mine in the *British Medical Journal*, under the title of "Conductive Anesthesia by the Intracanalicular Extradural Injection of Procaïn." Allow me to point out an inaccuracy in this abstract. I did not say that the method described is a new one. It was attempted nearly twenty years ago by Cathelin, and has been used from time to time since then by different French and German surgeons, with varying degrees of success. It has given best results in the hands of Americans, among others Dr. W. E. Faulkner of Boston, from whom I learned the technique in 1914. My statement was that, so far as I had been able to discover, the method was not in use anywhere in this country (England). I find that I am mistaken in this, and that Mr. Percival Cole has been using it recently at the Cancer Hospital, London.

I should be grateful if you would publish this letter, that I may not appear to claim indirectly a priority which does not belong to me.

SAMUEL R. MEAKER, M.D., M.R.C.S. (Eng.),
Esher, Surrey, England.

The Profession in the War.—We have passed through a time which, thank God, we shall never see again, under a strain which we perhaps did not really appreciate till it was relaxed. Looking back upon it all, we can say, first, that without any doubt whatever the medical work of the army was extraordinarily well done; second, that those at any rate who were connected with hospitals learned more than they ever learned before; and, lastly, that perhaps the greatest lesson of all was that over this wide area and throughout this immense body of men there was a unity of effort and a fellowship of spirit such as we had never before imagined could exist.—Major General Sir Wilnot Herringham, C.B., M.D., *British Medical Journal*, Jan. 4, 1919.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

WAR RISK INSURANCE

To the Editor:—Just a few words of disagreement with your endorsement of War Risk Insurance in *THE JOURNAL*, August 23. Yours is the first favorable comment I have read, while the complaints are unceasing.

1. If the bureau were efficiently managed, as it is not, the plan would still be a poor one. It arbitrarily dictates what persons may be beneficiaries, and it does not pay cash.

2. Why advertise low rates on \$1,000 of insurance, when they are in fact high rates on the amount of insurance actually given? In the twenty years, if the beneficiary live that long, the government gets back in interest on \$1,000 (deducting the payments each month) over 50 per cent. of what it pays out.

3. Now as to naming beneficiaries: My nearest living relative is an aunt. I was told she could not be a beneficiary eight months after I had applied for insurance. I was glad I had stopped my payments five months previously. The three premiums I did pay I charge to bitter experience.

STUART E. MANDVILLE, M.D., New York.

ANSWER:—This letter was referred to the Bureau of War Risk Insurance, which replies:

1. The bureau has repeatedly recommended to Congress that the War Risk Insurance Act be changed so as to enlarge the permitted class of beneficiaries to include uncles, aunts, foster parents, etc. There is at present pending in the House of Representatives (H. R. 8778) a bill to amend and modify the War Risk Insurance Act in this and other particulars. If this bill becomes law, the insured under a United States government policy may elect to have the insurance paid in a lump sum to the beneficiary, or in monthly payments covering a period of not less than thirty-six months.

2. Your correspondent assumes that the government pays no interest on the unpaid instalments of the insurance during the twenty year period. Section 402 of the War Risk Insurance Act provides "That . . . all calculations shall be based upon interest at three and one-half per centum per annum. . . ." As a matter of fact, the bureau pays interest at 3.5 per cent. on all unpaid instalments; \$5.75 per month for twenty years amounts to \$1,380.

3. As stated above in answer to the first comment, the bureau has no discretion in the matter of the permitted class of beneficiaries. Section 402 of the War Risk Insurance Act provides: "The insurance shall be payable only to a spouse, child, grandchild, parent, brother or sister, and also during total and permanent disability of the injured person, or to any or all of them." The application for insurance in favor of an aunt, was, of course, invalid; and the premiums paid in may be recovered by writing to the Insurance Division, Bureau of War Risk Insurance, setting forth the facts, and giving the full name, rank and organization at time of applying for the insurance, and Army serial number if in the Army.

DEATH BY HANGING

To the Editor:—I am anxious to obtain information: (1) as to what lesion of the spine usually occurs after hanging; (2) as to how soon death ensues.

C. J. HAMBREGER, M.D., Watertown, Wis.

ANSWER:—1. The pathologic effects of hanging are partly those of strangulation, to which must be added the effects of the weight or fall of the body. It is possible, therefore, that death may occur without any lesion of the spine whatever, although it is quite common to have injury of the spinal cord or medulla by dislocation of the vertebrae or fracture of the odontoid process of the axis. The findings depend on a number of factors, including length of drop, weight of body, adjustment of noose, etc.

2. If the neck is broken death is immediate; in the majority of instances, however, asphyxiation is the cause of death. This may require anywhere from one minute to a much longer time—heart beats sometimes persisting for from ten to twenty minutes. The mechanism has been classified by Peterson and Haines' textbook of Legal Medicine and Toxicology into three stages: first, quietude, consciousness being possible, lasting from a few seconds to one or one and one-half minutes; second, the stage of respiratory efforts and convulsive movements, with unconsciousness lasting from two to four or five minutes; third, the stage of almost absolute quiescence, varying from a few minutes to as much as fifteen minutes before death finally ensues.

Report of Seventh Examination of the National Board of Medical Examiners

The seventh examination of the National Board of Medical Examiners was held in Philadelphia, June 2-7, 1919. The subjects of the examination and the relative value of each were: anatomy, 100; physiology, 75; chemistry, 75; pathology, 75; bacteriology, 50; materia medica, pharmacology and therapeutics, 75; medicine, 200; surgery, 200; obstetrics and gynecology, 75; hygiene and sanitation, 50; medical jurisprudence, 25. A percentage of 75 was required to pass. Falling below 65 per cent. in two subjects, or below 50 in one subject, constituted a failure.

There were seventy-three applicants who applied for examination. Sixty-five were found to have the essential preliminary and medical qualifications, and fifty-two of these appeared for examination. Of these, fifty-one passed, and one failed. The following colleges were represented:

Name	Passed	Year of Grad.
J. Alston Moore, University of Penna.	1918	1918
Samuel E. Stokes, University of Penna.	1918	1918

* The general average of the candidates is based on subject values as rated by the board.

EXAMINATIONS AND TIME ALLOWED

Subject	Written	Kind of Examination	
		Other, and Remarks	
Anatomy.....	4 hours	Oral with prepared spec. 24 min. for each candidate.	
Chemistry.....	4 hours	Three hours laboratory in physiological chemistry.	
Physiology.....	4 hours	Laboratory 2 hours.	
Pathology.....	4 hours	Laboratory 4 hrs., 9 min. each cand.	
Bacteriology.....	2 hours	Laboratory 2 hours.	
Material medica, pharmacology and therapeutics.....	4 hours	Laboratory 2 hours.	
Obstetrics and Gynecology.....	4 hours	Clinical lab., 1 hour each cand.; clinical med., 3 hours.	
Medicine.....	3 hours	Lab. op. surg., 4 applied anatomy, 5 hours; clinical exam., 2 hours.	
Surgery.....	3 hours	Clinical exam., 3 min. each cand.; clinical exam., 30 min. each cand.	
Eye, ear, nose and throat.....			
Dermatology.....			
Obstetrics and gynecology.....	3 hours		
Hygiene.....	2 hours		
Medical jurisprudence.....	2 hours		

The examination consisted of written, oral, laboratory and clinical tests. The questions asked were as follows:

ANATOMY

Written Examination.—1. Describe the knee-joint with overlying structures and muscular attachments in immediate vicinity. 2. Describe the peritoneum. 3. Give attachment, action and nerve supply of following muscles: constrictor, pectoralis major and latissimus dorsi. 4. Name nasal accessory sinuses and locate openings from each into nasal cavity. 5. In simple fracture of femur in middle third, give anatomic reasons for difficulty in retaining fragments in apposition.

Oral Examination.—This was conducted with the use of specimens of the brain, osseous system and internal organs and specially prepared dissections demonstrating the gross anatomy of joints, and definite regions of the body; the identification of four specimens of histology under the microscope.

PHYSIOLOGY

Written Examination.—(Answer five questions): 1. Discuss the physiologic function of the pylorus in digestion. 2. Describe the origin and function of secretin. 3. Define periodic breathing, name the types of periodic breathing, discuss the causes of the same. 4. Discuss the propagation of the heart-beat in the mammalian heart. Define auricular fibrillation. 5. Illustrate by graphic tracings the effect on respiration, heart-rate and blood-pressure (a dog being used for demonstration). (a) Electrical stimulation of the vagus. (b) Intravenous injection of epinephrin (2 cc. 1:100,000 solution). To what is the change in blood-pressure due? (c) Intravenous injection of digitalis (alcohol-free tincture). How does the blood-pressure curve differ from that produced by the intravenous injection of epinephrin? (d) Inhalation of amyl nitrite (tracheal cannula). Explain change in blood-pressure curve. 6. Describe in detail the physiology of the parathyroid glands.

Laboratory Examination.—Each candidate was expected on tracings of the arterial and venous pulse from normal and abnormal cases, blood pressure readings, and heart sounds.

PHYSIOLOGICAL CHEMISTRY

Laboratory Examination.—To each candidate the following specimens were assigned: 1. Four samples of urine. Make a complete qualitative examination (clinical and microscopic) and report results with conclusions. If sugar be found in any specimen determine the amount. 2. Two samples of gastric contents. Test for acids and if free hydrochloric acid be found estimate the amount. 3. Two samples of blood serum. Remove all proteins; prove that this has been done, and after the removal of the proteins ascertain whether or not non-protein nitrogen exists in the specimen. State the methods used and the methods employed and the conclusions drawn from these findings.

MATERIA MEDICA AND THERAPEUTICS

Written Examination.—(Answer five questions): 1. Name two organic preparations of arsenic, and give the dosage, mode of administration and indications for the use of each. 2. (a) Give the source and physical properties of salicylic acid. (b) Give three therapeutic uses of this drug. (c) Write a prescription containing a preparation of salicylic acid, with full directions to the patient, to which the same is intended. 3. (a) In which forms of heart disease should digitalis be used with caution, and why? (b) In which types of circulatory disturbance does digitalis exert its best therapeutic effect? 4. Name three drugs classed as antipyretics and explain the antipyretic action of each. 5. Discuss the relative value of iron and arsenic in anemia. 6. (a) Discuss the constipating effect of opium. (b) Describe the effect of morphia on the respiratory center. (c) Explain the analgesic effect of morphia.

PHARMACOLOGY

Practical Examination.—1. Into a lymph sac of one frog inject 1 cc. of Solution A into anterior, 1 cc. of Solution B into posterior, and briefly describe symptoms developing in the following fifteen minutes. Identify action exhibited; identify the drugs or the group to which each belongs. (Solution A was strychnin; B was chloral hydrate; strengths chosen so that symptoms developed in five to eight minutes.) 2. Into the right eye of Rabbit C have been instilled several drops of Drug Solution C. Into the right eye of Rabbit D have been instilled several drops of Drug Solution D. Note the drug and its action. (Solution C was cocaine; D was atropin.) 3. Examine Tracing 1, showing arterial blood pressure and contractions of right ventricle, made with mercury manometer and myocardiograph, respectively. What is the drug and what structures have been acted on to produce these results? (Digitalis.) 4. Examine Tracing 2, showing arterial blood pressure and contractions of right ventricle. What statement can be made concerning the pressure in the right ventricle? What are the signs of slight dilated, brachy vascular respiration, and increased transmission of voice sounds (Nitroglycerin, chloroform.)

OBSTETRICS AND GYNECOLOGY

Written Examination.—1. Describe the normal mechanism of labor in a face presentation, and outline the treatment: (a) When the case is seen early in labor. (b) When seen late in labor. 2. Diagnosis, treatment and possible sequelae of hydramnios. 3. What are the causes and describe the diagnostic signs of threatened rupture of the uterus? What is the treatment after rupture has occurred? 4. Describe two varieties of contracted pelvis and the technique of pelvic mensuration. 5. Give in detail the local and general treatment of metrorrhoeal sepsis which the physician is seen early in. 6. Treatment of a case of partial heart-block at age 35, with enlargement of the heart, myocardial degeneration, and arteriosclerosis, all of moderate degree, and with symptoms of beginning lack of compensation. 7. A man of 28 years, employed in the manufacture of painting wheels. What are the signs of slight dilated, brachy vascular respiration, and increased transmission of voice sounds (Nitroglycerin, chloroform.)

Oral Tests. During the written examination, each candidate was required to make demonstrations on the manikin and to explain different obstetric operations.

MEDICINE AND MEDICAL JURISPRUDENCE

Written Examination. 1. (a) Describe the Stokes-Adams syndrome, and the mechanism of heart block. (b) Mention the symptoms and physical signs of partial heart block. (c) Treatment of a case of partial heart-block at age 35, with enlargement of the heart, myocardial degeneration, and arteriosclerosis, all of moderate degree, and with symptoms of beginning lack of compensation. 2. A man of 28 years, employed in the manufacture of painting wheels. What are the signs of slight dilated, brachy vascular respiration, and increased transmission of voice sounds (Nitroglycerin, chloroform.)

at the right apex of the lung. No rales are heard. Tubercle bacilli are not found in the sputum. (a) Discuss the diagnosis, and state what symptoms and other physical signs will, if found to be present, affect the diagnosis. (b) Complete a clinical picture by a careful selection from the symptoms and physical signs mentioned by you in (a); then state your diagnosis and outline treatment. 3. A man of 50 years has well-advanced chronic interstitial nephritis; a moderately enlarged, but well-contoured heart, without murmurs; and moderate arteriosclerosis. Systolic blood-pressure, 210; diastolic, 120. (a) Outline diet, medical treatment, and general regimen—give your reasons briefly. (b) Prognosis as to probable duration and cause of death. 4. A male patient, aged 45, has had a severe attack of indigestion accompanied by constipation and gripping abdominal pain. (a) On what criteria would you decide whether or not this is a case of chronic appendicitis? (b) Assume that the diagnosis of chronic appendicitis is the most probable one; discuss briefly the location of operation, and the basis on which you would make a surgical opinion. (c) Define leukemia and discuss the classification of the varieties of this disease. (d) Give the blood picture of two varieties of leukemia. (e) Discuss the probable course, prognosis and duration of each case presented in (d). 6. During an epidemic of acute poliomyelitis you are called to attend a child of 6 years, acutely sick with fever and vomiting. (a) Describe the procedure to determine whether this disease exists. (b) On what results of such investigation would you establish a positive diagnosis? (c) Discuss the treatment of any resulting paralysis by medicinal means, electricity, and physical therapy at different stages of the paralysis. 7. Give the incubation period, and mention three important diagnostic points in each of the following diseases: (a) scarlet fever; (b) measles; (c) smallpox; (d) diphtheria. (e) typhoid fever. 8. A case of erythema multiforme is discovered at a mobilization camp. Describe the measures that should be adopted to prevent the spread of the disease. 9. (a) State how you would determine that a person is actually dead. (b) What conditions simulate death? 10. (a) Define an hallucination and delusion, indicating the differences between the two. (b) Give an illustrative example of each.

Clinical Laboratory.—Each candidate was required to describe and diagnose the following: 1. Urine sediments; report findings. 2. Stained smears from a group containing: peritonsillar abscess; acute rheumatic fever; leukemia; splenomegaly; lead poisoning; tertiary syphilis. Diagnose and give reasons for same. One stool washing from a group of three, containing in addition to the usual vegetable debris, meat fiber, etc., the following ova: *Taenia saginata*; *Ascaris lumbricoides*; *Oxyuris vermicularis*; *Uncinaria americana*; *Ascaris lumbricoides*; *Trichostrongylus trichiuris*.

Clinical Examination.—This was held in the wards of the Philadelphia General Hospital, each candidate being assigned a long case for a physical examination, asked for the laboratory or special findings, and asked to conclude and stand a quiz on the case. Following this the candidate was assigned to short cases representing some well defined condition, as pleural effusion, enlarged heart, aneurysm, large liver, ascites, etc., to test physical examination methods. The clinical conditions included: aortic insufficiency, splenomegaly, acute endocarditis, severe anemia; syphilis, double aortic disease, dilated hypertrophy of heart, arteriosclerosis, chronic nephritis mitral insufficiency, chronic interstitial nephritis, hypertrophied heart, lungs, gastric syphilis, atelectasis, old tuberculous, cardiac asthma, acute rheumatism, acute rheumatoid arthritis, pleural effusion, essential asthma, cardiac enlargement, pernicious anemia, carcinoma of stomach, diabetes, hypochlorhydria, acute rheumatism, nephritis, auricular fibrillation, ascites, chronic rheumatism, aortic regurgitation, aortic stenosis, mitral regurgitation, enlarged liver, emphysema, aortic and mitral diseases, old bronchitis, thickened pleura.

HYGIENE

Written Examination.—1. Describe a sanitary dairy. 2. Discuss approved methods of ventilating a heating hospital in a temperate climate. 3. Discuss the selection, construction and administration of a detention camp for the control of bubonic plague. 4. What are the essential factors in providing for the hospital care of contagious diseases and the construction and administration of a hospital? 5. Contrast the insect transmission of typhoid fever and malaria.

SURGERY AND DERMATOLOGY

Written Examination.—(Answer seven questions in surgery and one in dermatology.) 1. Diagnosis, differential diagnosis and treatment of concussion of the brain. 2. Diagnosis, differential diagnosis and treatment of carcinoma of the tongue. 3. Discuss deep cervical suppuration. 4. Discuss the prognosis of gunshot injury of the solid organs of the abdominal cavity and describe the treatment of wounds of the kidney involving the hilum. 5. Discuss the differential diagnosis between an infected gallbladder and chronic gastric ulcer. 6. How is the occurrence of ankylosis after injury to a joint explained and give in detail the surgical methods of restoration of function after ankylosis of a joint. 7. Discuss the surgical management of a compound, comminuted, infected fracture of the middle third of the humerus. 8. Discuss tetanus.

DERMATOLOGY

9. Give the differential diagnosis (skin only): (a) Between smallpox and vulgar syphilis; (b) Between smallpox and chickenpox. 10. Describe: (a) vegetable parasitic disease with general distribution. (b) one animal parasitic disease with general distribution. (c) give differential diagnosis between diseases described in A and B.

SURGICAL PATHOLOGY

During the written examination each candidate was given a laboratory examination in surgical pathology. The specimens were selected from the following: carcinoma of breast, chronic cyst mastitis, fibro-sarcoma of breast, acute carcinoma cholecystitis, colloid cyst, hypertrophy prostate, carcinoma of jaw.

Laboratory Examination in Operative Surgery. Each candidate was given one operation on the cadaver selected from the following list: trephine; tracheotomy; thoracotomy; appendectomy; lateral intestinal anastomosis; inguinal hernia; suprapubic hysterectomy; amputation of arms, forearms, fingers, thigh, leg, and foot; and also a practical examination in regional anatomy.

Clinical Examination.—This was held in the wards of the Philadelphia General Hospital, each candidate was given at least three cases and these were chosen from the following: fracture of head of humerus; fracture of humerus, involving circumflex nerve; fracture of hip; fracture of tibia and fibula; fracture of femur; supracondylar; leg ulcers; abscess of the neck; cervical adenitis with bilateral sinusitis; tuberculosis of hip; destruction of head and neck of femur; tuberculosis

of knee; tuberculous glands of neck; gangrene of stump from recent amputation; contraction from infected hand; old curvature of spine; bad union of Pott's fracture; dislocation of radius; dislocation of hip joint following arthritis of hip joint following influenza; osteomyelitis of femur; chronic empyema; epigastric median hernia; operated hernia; mass in scrotum; inguinal hernia; umbilical hernia; carcinoma of stomach; gastric ulcer; appendicitis; arthritis deformans (chronic); monarthritides of knee, gonorrheal; gallbladder disease (cholelithiasis).

PATHOLOGY

Written Examination.—(Answer five questions.) 1. Describe the mode of spontaneous cessation of hemorrhage, indicating the factors involved; what differences in the fate of the escaped blood in a nonfatal hemorrhage into the peritoneal cavity as contrasted with a hemorrhage into the midst of the body tissues. 2. Describe the steps of formation and the gross and microscopic features of the contents and wall of a staphylococcal abscess; indicate what is meant by "pointing" of an abscess and how accomplished. 3. Name at least three types of "benign" and an equal number of "malignant" neoplasms; what features are concerned in the "malignancy" of a tumor; discuss briefly in what ways and under what circumstances a "benign" tumor may seriously affect the well-being of the life of the host. 4. What structural changes are believed essential to the establishment of "diabetic diabetes mellitus", what noxious substances are present in the blood underlying diabetic convulsions and coma, and how are they believed to act to induce such phenomena. 5. Describe the gross features of at least one anatomic variety of bronchiectasis; what factors are involved in the causation and development of bronchiectasis; what types of respiratory symptoms are apt to induce; and what serious complications are to be feared from the existence of bronchiectasis. 6. Describe the gross features of a kidney the seat of a pyelonephrosis, supposing, as frequently, the condition is secondary to a suppurative in the lower urinary tract or vicinity; indicate the paths of the "ascending infection" and how are the pyogenic organisms distributed to and into the kidney and pelvis.

Laboratory Examination.—During the written examination each candidate was given gross specimens and microscopic sections chosen from the following: acute fibrinous pericarditis; chronic fibrinous adhesive pericarditis; anthracosis of lung; several specimens of tuberculosis of lung; chronic cirrhosis of the liver; intussusception of small intestine; tuberculous mesenteric lymph nodes; melanotic sarcoma of liver; multilocular glandular cystoma of ovary; aneurysms of aorta; senile and syphilitic arteriosclerosis; lobar pneumonia; sclerotic mitral valvulitis (austrioid mitral); carcinoma of the stomach; carcinoma of the lung; chronic fibrous pleurisy; hypertrophy of heart; chronic interstitial nephritis; anemic infarct of spleen; scirrhus carcinoma of stomach; uterine fibroid.

Microscopic: bronchopneumonia; miliary tuberculosis of lung; cirrhosis of liver; acute fibrinous pericarditis; scirrhus carcinoma of stomach.

BACTERIOLOGY, IMMUNITY AND MEDICAL ZOOLOGY

Written Examination.—1. (a) Briefly discuss, without giving technique, the question of laboratory diagnosis of typhoid fever, especially as to the value of the various methods of culture and microscopy. (b) Give sources of milk contamination to be considered in the epidemiology of a typhoid fever outbreak. 2. *Plague.* (a) Give more important morphologic and cultural characteristics of the plague bacillus. (b) Give a brief outline of the history of the plague in the world. 3. (a) Give laboratory procedures necessitated in the diagnosis of bubonic plague. (b) Give the names of bacteria and molds which may be found in a smear made from the throat, and which of these would fail to grow in culture on a Löffler blood serum slant. (c) What findings in a smear establish the diagnosis of Vincent's angina? 4. (a) What do you understand by (1) antigen, (2) passive immunity, (3) macrophage, (4) immune body, (5) homologous serum? (b) Give a general idea of the method of establishment of the diphtheria antitoxin unit. 5. *Tape-worms.* (a) Give names and general points of distinction of the four commonest tape-worms of the human intestine. (b) Give the large human tapeworms. (c) Is man the intermediate or definitive host for the cestodes above noted in (b)?

Laboratory Examination.—The examiner is provided with tubes, plates, etc., of various standard culture mediums. The condition is explained as to the composition, uses, technique of inoculation and study of same. There are also provided plates of plain agar, blood agar, etc., showing colonies, and the candidate is examined as to his ability to recognize and discuss colony characteristics with the unaided eye and magnifying glass. The candidate is also examined as to interpretation of gas and acid production on fermentative tubes, staining, microscopical, serological, physiological, such as Wassermann, or other complement fixation tests, microscopic agglutination, precipitin reactions, etc., are provided and interpretation required of same. Specimens of intestinal parasites and ova of same, together with stained smears of blood preparation, of parasites will be given the candidate for identification.

A British View of the Needs of Medical Education

In a memorandum published late in 1918 Sir George Newman, chief medical officer of the London Board of Education, made the following statement relative to the most essential needs in medical education as revealed by the world war:

"There must be from time to time, and in accordance with the direction and establishment of new medical knowledge or the requirements of the times, reasoned effort to eliminate the unnecessary and the redundant and to concentrate upon the essential things. . . . All through the curriculum we need to impose less on the memory of the student, and seek rather to draw out his mind and faculties, his interest and perception, compelling him to do things for himself with his own hands and his own head, and to observe and experiment, to study intensively rather than extensively, to think and wonder and investigate for himself. This is to educate him and give him independence, to add experience to knowledge

and wisdom to experience, and above all to foster the love of learning." Sir George emphasized the following points:

(a) Be strong in physiology, anatomy, and pathology—the bed rock of medicine.

(b) Have a thorough training in physical signs and clinical examination.

(c) Concentrate more on outpatient department, on children's ailments, on subjective symptoms and on anything which will bring the student into personal touch with the beginnings of disease.

(d) Pay wider attention to the question of therapeutics, nonmedical as well as medicinal.

(e) Lay special stress upon preventive medicine, dealing with ordinary as well as infectious diseases. In other words death under fifty must be prevented.

(f) Provide for efficient postgraduate teaching.

Book Notices

THE OPERATIVE TREATMENT OF CHRONIC INTESTINAL STASIS. By Sir W. Arbuthnot Lane, Bart., C.B., Consulting Surgeon to Guy's Hospital. Fourth edition. Cloth. Price, \$5. Pp. 328, with 133 illustrations. New York: Oxford University Press, 1918.

This edition is simply another impression of the former edition so far as the work done by the author is concerned. The only difference between the two editions is the addition to the present one of a few short chapters by various writers which are intended to lend support to the theory advanced by the author. All of the extravagant claims made in the former edition were thoroughly reviewed at the time, and as there has been no change made in the views of the author and no new evidence offered to support those views, it is unnecessary to repeat what was said concerning them in the former review.

MALARIA AND ITS TREATMENT IN THE LINE AND AT THE BASE. By Capt. A. Cecil Alport, R.A.M.C., M.B., Ch.B., Officer in Charge of Medical Division of the 28th General Hospital, Salonika. Cloth. Price, \$6. Pp. 279, with illustrations. New York: William Wood & Co., 1919.

This book is based on personal observations and experiences. It was written under active service conditions when the author had practically no access to the literature. The requirements of the busy practitioner have been kept in view, the language is simple, and there are numerous instructive illustrations. The chapters on the clinical features of malaria and on the treatment of its various forms contain many accurate and detailed clinical histories, and should be of value and interest to physicians in malarial districts. The price seems excessive.

RÖNTGEN INTERPRETATION. A Manual for Students and Practitioners. By George W. Holmes, M.D., Roentgenologist to the Massachusetts General Hospital, and Howard E. Ruggles, M.D., Roentgenologist to the University of Chicago Hospital. Cloth. Price \$2.75. Pp. 211 with 151 illustrations. Philadelphia: Lea & Febiger, 1919.

This book is intended to give the essentials of roentgen interpretation. It is designedly elementary. There is a mere outline of each of the subjects. The descriptive text covers not more than ninety pages, though the subjects include the roentgenography of bones with their many diseases—one half of the book of the heart, lungs, stomach, bowel, kidney, bladder, in fact, the entire body. One cannot expect finished details in any branch to be included in such a small compass; one must consult larger works or works on special topics. The book, however, abounds in valuable suggestions, helpful even to the expert. And its conservatism and caution are to be most warmly commended. No rash conclusions are drawn from roentgenograms as to gallstones, pulmonary tuberculosis or inflammatory lesions of bone; the numerous possibilities of error are constantly kept in sight. A wise emphasis is placed on the necessity of an understanding of normal anatomy and of pathology before the student or practitioner attempts to interpret roentgenograms. And the same position is taken that the roentgenogram is only one method of diagnosis and is, if properly used, to be linked with others, such as bedside and laboratory examinations. We note very scant reference in the bibliographic lists to other than

American or English articles. This is a serious lack, particularly if it implies that French, German and other continental writers have not been freely consulted. The illustrations are, in general, good; some are poor. More lettering, the more frequent use of arrows indicating lesions, and legends that are more descriptive would make the illustrations more helpful—they are for students and untrained physicians, it should be remembered. Several typographic errors attracted our attention. Some incorrect Latin forms have been used, as *pelvics*, *diverticulo*. And such expressions as "specific stomach," "chronic appendix," are too colloquial to find a place in a book, supposedly written in dignified and correct English.

Social Medicine, Medical Economics and Miscellany

REPORT OF THE PENNSYLVANIA HEALTH INSURANCE COMMISSION

The report of the Health Insurance Commission of Pennsylvania, just issued, is necessarily a limited one. The commission was directed by the act of July 25, 1917, to investigate "the extent, loss and causes of sickness and accidents of employees and their families not covered by the workmen's compensation act; the adequacy of the present methods of treatment and care of such sickness or injury; the adequacy of the present methods of meeting the losses caused by sickness or injury, either through insurance or otherwise; the influence of working conditions on the health of employees, and the methods of sickness prevention with a view to recommending ways and means for the improvement of the health of employees and their protection against sickness and accident," and for all this work the legislature provided the liberal appropriation of \$5,000. Naturally, the commission was not able to make any investigation, but confined itself to collecting and arranging material gathered by other agencies. It reports that there are constantly ill in the state more than 385,000 employees, of whom approximately 140,000 are subjects of severe illness and 245,000 less serious. The average loss of working time on account of sickness is at least six days per annum for each employee. Regarding physical fitness, Pennsylvania had the highest percentage of any state in the Union, of men rejected for physical reasons in the draft, 46.67 per cent. of young men examined between the ages of 21 and 31 years being found physically defective. The average for the whole country was 29.11 per cent. Death rates in Pennsylvania are also higher than the average, the infant death rate being particularly high in the large cities. In 1917, the infant death rate for Philadelphia was higher than that of New York, Brooklyn, Boston or Chicago, while Pittsburgh ranked second among the cities of its class. The state as a whole had an infant death rate in 1916 of 114 per thousand, as compared with an infant death rate of 101 per thousand for the registration area.

Regarding financial loss due to sickness, the commission estimated the wage loss to employees at \$33,000,000 a year. The losses to employers consist of decreased production and cost of labor turnover. During the influenza epidemic, anthracite coal production in Pennsylvania, the largest coal producing state in the Union, dropped 500,000 tons in a few days. The losses to the community consists of direct money loss and social loss. The state spends more than \$9,000,000 each year directly for the treatment of sickness, and \$4,000,000 for the maintenance of institutions for the care of defectives. In addition to public institutions, 175 hospitals report that in 1916, 57 per cent. of their patients were treated free. The commission finds that wage earners are not receiving satisfactory medical care. Hospital accommodations in the state average a little more than one-half the recognized minimum of five beds per thousand. Approximately one-fourth of those actually disabled by sickness never receive medical care. Insurance protection against sickness was

found among only 30 per cent. of employees. The lower the wage group, the least likely the insurance protection. Such insurance as was carried seldom provided proper medical care. Lodges, fraternal societies and trade union funds afford little better protection.

The commission is of the opinion that industry is clearly responsible for a large proportion of the illness among employees; that fully one half of the existing sickness could be eliminated by proper preventive methods; that from 70 to 75 per cent. of the schoolchildren of the state are physically defective, and that most of the defects are or were correctable; and that a large number of communities in the state have no active health work nor adequate appropriations for health activities. Regarding responsibility, the commission holds that this rests on three groups, the community, the industry and the individual, and that at present these groups are meeting the losses for illness in unequal share. The burden on the individual is often disastrous and out of proportion to his individual responsibility or ability to carry it, and some means of a just distribution of this burden should be found. There is in Pennsylvania today, in the opinion of the commission, urgent need for a program that will provide efficient care for employees and their families when ill and preventive measures that will as far as possible prevent illness and increase the health and vigor of the citizens of the state. No definite health insurance measures were recommended by the commission. Instead, it recommended that a new commission be appointed to continue the investigation and to study proposed and existing schemes of health insurance in this and other countries with a view to formulating definite measures. The appropriation of \$5,000 for such a commission was, of course, ridiculously inadequate. The problem as shown by the report of the commission would justify the expenditure of any amount of money for a clearer understanding or a solution of the problem.

SCHOOL HYGIENE, CHILD LABOR AND HOUSING IN ITALY

A report on school hygiene, child labor and housing in Italy has just been issued by the Commission for Tuberculosis of the American Red Cross in Italy following eight months' work of investigation carried on with groups of Italians. The fields selected for study were chosen because in them are found the conditions that are the underlying causes not only of tuberculosis but also of other maladies, and because it was realized that a knowledge of what had been accomplished in the great social movements of the country would be indispensable to an intelligent promotion of the activities of the commission.

The objects, in the field of school hygiene, were to promote the physical examination of all schoolchildren, the correction of physical defects, the sanitation of the school environment, the teaching of hygiene, and the establishment of health habits in the school age. The commission enlisted in the work the Italian School Hygiene Association, promising financial support of any worthy project. A comprehensive study of the schools was made and an ideal program formulated. The sympathy of the ministry was secured, propaganda widely disseminated, and arrangements made for the publication of children's textbooks on hygiene, to be used in the schools.

Child labor, it was found, does not constitute a separate social problem in Italy. There is little legislation directed against it, as such; what regulations exist are not enforced. The commission, in its extensive study of conditions, compiled the inadequate available statistics pertaining to child labor, and recommends, as Italy's chief needs: laws to govern agriculture, commerce and homework; improvement in health rules; medical examination; raising of the working age, which is 12 at present; shortening of hours, and strengthening of the inspecting force.

The housing situation is an anomaly. Conditions in larger cities could hardly be more wretched. Age, damp, filth, dark and overcrowding characterize the dwellings. Toilet facilities, baths and means of garbage disposal are urgent necessities to relieve the filth of surroundings and make cleanliness

possible. Yet more actual work is being accomplished in Italy in providing better housing than in any other country. Most comprehensive plans of destruction and reconstruction are being put in execution in several cities. The commission urges as the primary and most essential need a campaign of education in habits of personal cleanliness.

The report emphasizes the necessity of laying a foundation for international public health activities.

Medicolegal

Evidence and Instructions in Malpractice Case

(*Dameron v. Anastro (Calif.)*, 178 Pac. R. 874)

The District Court of Appeal of California, Third District, in reversing a judgment that was rendered in favor of the defendant, says that the plaintiff, a physician, sued the defendant for professional services, and for room, board and nurse hire, while the defendant wanted damages for alleged malpractice. The defendant, in a collision with a train, had suffered ten fractures of the legs and arms, and was, at his own request, taken to the plaintiff's hospital. He claimed that when, after nearly ten weeks of otherwise successful treatment, the plaintiff undertook to reduce adhesions in the knees, he negligently rebroke some of the original fractures. But one carefully and impartially reading the voluminous record could hardly resist the conclusion, the court thinks, that the verdict ought to have been for the plaintiff physician. At any rate, the jury should have been instructed, as requested, that he was entitled to recover the reasonable value of the use of the room and of board and nurse hire, regardless of the question whether he used ordinary care and skill in the treatment of the defendant.

Probably the most serious error consisted in giving the jury an instruction which completely ignored the test fixed by the law based on the methods and practice of the school to which the plaintiff belonged, and permitted the jury to apply its own standard of care or that of each individual juror to the treatment accorded the defendant by the plaintiff. It made no difference that other instructions may have presented the correct standard, as that would simply be an instance of an irreconcilable conflict.

As to the nature of the treatment required and the amount of force that might be exercised to break such adhesions as existed in this case, manifestly, only an expert could properly determine and testify. But an instruction proposed was faulty as implying that only an expert could testify as to the amount of force that actually was used and the method of treatment that was actually employed. As to what occurred, of course, the nonexpert was as competent as the expert witness. If there had been no dispute as to the facts it would have been a question solely for the physicians and surgeons. But it was not error to refuse the instruction, there being a conflict as to the facts.

An instruction was requested to the effect that the question of whether the plaintiff was negligent in his treatment of the defendant was to be determined by finding whether or not he possessed and used that degree of skill and learning possessed and used by physicians of the same school practicing in the same or similar localities. Such standard is clearly established by the authorities, and the trial court might well have given that specific instruction, even if it was substantially covered by other instructions that were given, when construed together.

Considerable latitude must be allowed in the choice of facts as the basis of hypothetical questions, and if the question is fair, and understandable by the witness, it is not to be excluded because it does not comprehend all of the important facts in the case; and if objection is made to it because it does not, the objection should specify the additional facts which ought to be included. Declarations of the physician at the time of the treatment are admissible in evidence, and may be included in a hypothetical question; but statements of

an assisting physician "to go easy," etc., should be left out, being incompetent.

This court does not understand that the plaintiff was denied any legal right by not being allowed to illustrate his testimony by means of a human skeleton. It is a matter left to the sound discretion of the court. No doubt such object may often be properly used to make more intelligible the testimony of an expert. It falls within the same category as pictures and diagrams.

Evidence that the plaintiff was a member of a county medical association was not admissible for the purpose of showing that the association protected any member in litigation brought against him in a case of the present character.

A rehearing was denied by the Supreme Court of California.

Evidence of Physician's Bill

(*Quirk v. Metropolitan St. Ry. Co. (Mo.)*, 210 S. W. R. 106)

The Kansas City (Mo.) Court of Appeals, in affirming a judgment in favor of the plaintiff for medical attention and other damages suffered by him on account of injury to his son, holds that the trial court did not err in admitting in evidence a written statement, consisting of the physician's bill, obtained from the physician's bookkeeper. The court says that the physician amputated the boy's leg and treated him for several months. The plaintiff went to see the physician to get his bill, but the physician was out of town, the plaintiff got the bill from the physician's bookkeeper, and this was introduced in evidence. This court thinks this statement was admissible as tending to show the amount of the bill. The physician's bill amounted to \$192. The physician was out of town at the time of the trial, and the plaintiff was allowed to testify, over the defendant's objections, that the bill was reasonable. The objection to the testimony was that no one but the physician was competent to testify as to the reasonableness of the bill, and that the witness' answer was a conclusion. The court thinks neither objection was sufficient. Of course, other competent witnesses could testify as to the reasonableness of the bill, and there was nothing to show that the witness was not competent to give his conclusion. There was no objection on the ground that it had not been shown that the witness was qualified to testify as to the reasonableness of the bill. There was also nothing in the contention that the physician's bill was barred by the statute of limitations. This court did not find that the point was raised in the lower court, but, aside from that, only the plaintiff could raise that point against the bill, as the bill was not barred unless the plaintiff chose to raise it.

Proper Time for Roentgen-Ray Evidence

(*Van Tonder v. Birmingham Railway, Light & Power Co. (Ala.)*, 80 So. R. 858)

The Supreme Court of Alabama, in affirming a judgment in favor of the defendant in this personal injury case, says that the plaintiff urged that a new trial should be granted because of newly discovered evidence resulting from a roentgen-ray examination of her back showing the nature and character of her injury and its probable cause. But the court does think that this was a good ground for granting a new trial, for one reason, because it is not persuaded that due diligence was shown in obtaining this roentgen-ray examination. The plaintiff relied, among other things, on permanent injuries to her spine, and it was but fair to herself, the defendant, and the court that she should have obtained and produced the best evidence on the subject; and the reasons for resorting to a roentgen-ray examination were as important before as after the trial. It is a matter of common knowledge that in cities the use of the roentgen ray for the discovery and diagnosis of internal injuries and abnormal conditions of the human body is of common occurrence. True, it may incur some trouble and extra expense, but the trouble and expense should be no greater before than after the trial, and the reasons and necessities for them should be as imperative for the original trial as for upsetting or overturning the verdict of a jury after it has passed on the issue to which the examination relates and which was contested on the trial.

AMERICAN SOCIETY FOR CLINICAL INVESTIGATION

Annual Meeting, held in Atlantic City, N. J., June 14, 1919

(Concluded from page 787)

Studies on Malaria Control

DR. C. C. BASS, New Orleans: The frequency of malaria infection without recognized symptoms was compared with the frequency of recognized attacks in an area of great prevalence. A malaria survey was made of 31,459 persons, practically everybody living in an area of 328 square miles in Bolivar County, Miss. Bolivar County is representative of the most heavily infected malaria section of the United States. Of the 31,459 persons included in the malaria survey, 40.30 per cent. gave positive histories. Blood examination of these revealed malaria parasites in 28.96 per cent. There were 59.70 per cent. who gave negative histories. Of these, 15.93 per cent. were found positive on blood examination. History of attacks alone cannot be depended on to indicate the presence of malaria infection. It indicates only 55.09 per cent. of the existing infection.

Metabolism in Leukemia and Cancer During Radium Treatment

DR. THOMAS ORDWAY, Albany, N. Y.: The application of radium over the enlarged spleen in leukemia exerts a marked influence on the protein metabolism, increasing the protein constituents in the urine, notably total nitrogen, urea, ammonia, and also to a very marked degree, the phosphates. The changes in the nitrogenous metabolism depend on the amount and nature of tissue autolyzed. Changes in the urine, as a result of radiation, are due, in part at least, to the products derived from the autolysis of the abnormal tissue under the influence of the radiation from radium. Only one patient showed systemic reaction because of the radiation, and in this instance the nitrogenous substance in the urine did not show as excessive increase as in leukemia which showed no general symptoms of toxemia.

Significance of Abnormalities in Form of Electrocardiogram

DR. G. CANNY ROBINSON, St. Louis: Certain abnormalities in the form of the electrocardiogram are recognized as evidence of faulty conduction of the cardiac impulse through the ventricles. These abnormalities consist of a prolongation of the time required to complete the first series of waves, the Q-R-S group of the ventricular part of the electrocardiogram and notching of the main wave of the group. I have seen cases which seem to prove that faulty conduction through the ventricles may depend on what has been termed functional fatigue. In one case, distinct improvement in the ventricular conduction followed slowing of the heart rate, when longer diastolic pauses were present. The rate of recovery of conduction was observed also in this case to become more rapid with improved circulatory efficiency. I believe that the disturbance of intraventricular conduction is

the result of the presence of acid metabolites in the ventricular structures, and that sclerosis of the coronary arteries and, perhaps, other lesions causing an insufficient blood supply to the ventricles are responsible for the presence of the acid metabolites, as it has been shown that these accumulate whenever the oxygen supply to muscle is inadequate. This hypothesis renders an anatomic lesion in the subendocardial structures unnecessary to account for the disturbance of the intraventricular conduction, although the effect of acid produced in the muscle on conduction is still open to question.

DISCUSSION

DR. HENRY SEWALL, Denver: The toxic origin of cardiac irregularity noted by Dr. Robinson suggests to me phenomena presented by a case I have followed for many years. The patient, a physician and a "tuberculosis cure," suffered a moderately severe attack of typhoid in 1896, at the age of 41. Following this, a "typhoid rib" gave trouble for a year or two, but yielded to curettement. During convalescence, pus and blood were passed with the urine, their origin being traced to the prostate. A rich culture of colon bacilli was made from the pus. The ingestion of hexamethylenamin gave remarkable relief and the abscess gave no trouble, except for occasional exacerbations at widely separated intervals. The succeeding years were marked, however, by much distress in the way of diffuse aching pain, myalgia, headache, nervousness and periodic prostrations with active sore throat in which the streptococcus was the chief offender. As nearly as can be remembered, shortly after recovery from the typhoid, the pulse began to be irregular at times, both in rhythm and in strength. The irregularity finally developed a character marked by a succession of from two to seven rapid beats of rate about 90 per minute, followed by a short pause, the next series being initiated by a beat much stronger than its successors. The irregularity usually subsided under mental excitement, physical exercise or with slight alcoholic stimulation. The pulse when regular ran about 70 per minute. In the spring of 1919, active symptoms led to examination of the prostate, and pus was expressed from it in abundance, the infective organism being the colon bacillus. Great improvement followed periodic massage of the organ. Since this treatment was begun, about four months ago, the pulse rate has been perfectly regular, with a rate of about 68, and the rheumatic symptoms have disappeared completely.

DR. J. C. MEAKINS, Montreal: The cases reported by Dr. Robinson are of great practical value in the interpretation of ventricular phases of the electrocardiogram. Such cases are not rare, and all variations may be found of the ventricular complex, from the slightly abnormal to those showing all the not rare, and all variations may be found of the ventricular interest in these cases, as pointed out by Dr. Robinson, lies in their temporary character, and seems to afford evidence of a more subtle change in the ventricular conducting system than that of gross anatomic damage.

Immunologic Experiments with Streptococci from Influenza

DR. E. C. ROSENOW, Rochester, Minn.: From a study of the effects of intratracheal injection of green-producing streptococci isolated in influenza and the accompanying pneumonia, we have found a strain or strains which possess marked and peculiar virulence. With these, the picture of influenza has been closely simulated in animals. A monovalent serum has been prepared in a horse by the injection of one strain isolated from the blood in a fatal case. The agglutinating power of this serum, type pneumococcus serum, hemolytic streptococcus serum, and normal horse serum, has been tested against numerous strains isolated from the sputum, throat, blood and lung exudate in cases of influenza. Specific agglutinations with the monovalent serum have been obtained in a large number of cases of influenza. The cases studied came from widely separated communities, most of the negative agglutinations occurring when the cultures were made during convalescence. However, this was true in a few instances in the early part of typical attacks. This specific strain, according to this test, tends to disappear promptly

during convalescence, and is rarely found in normal throats. Some of these strains, just as has been found to be the case with the streptococcus from poliomyelitis, lose their specific character promptly on cultivation, while others remain susceptible to specific agglutination months after isolation. Most of the specific strains do not ferment inulin and are not bile soluble. The agglutination experiments showed that the green-producing strains of this streptococcus from influenza are immunologically identical, or closely related. Single highly agglutinating strains have been found to absorb the specific agglutinins from the serum for all the strains. Non-agglutinating strains, including Type II pneumococci, remove little or no agglutinin. According to these tests, therefore, it appears that among the green-producing streptococci or diplostreptococci in influenza there is present a strain that has pandemic characteristics.

*Case of Human Rabies. J. C. Regan and A. Silkman, New York.—p. 237.

Diagnosis of Arteriosclerosis from an Ocular Standpoint. C. A. Clapp, Baltimore.—p. 257.

Symptoms of Hyperthyroidism Observed in Exhausted Soldiers. W. Johnson, R. A. M. C.—p. 260.

Case of Human Rabies.—Several points of value are emphasized by Regan in the discussion of his case. For instance: The best method of treating bites of suspected rabid animals is by cauterization with nitric acid which by virtue of its power of diffusibility and penetration may destroy the virus in cases in which other chemicals would have no effect. It is especially valuable in the cauterization of bites treated late. It produces little scarring and the resultant wound heals well. It is the caustic that should always be employed. To get the utmost effect the nitric acid must be "fuming." The wound should be cauterized as soon after the bite as possible, even up to the seventy-second hour after the accident. Previous to cauterization the wound should be squeezed to encourage bleeding, and it should be thoroughly washed with mercuric chlorid solution (1:1,000). A wet dressing of this should be applied after the cautery has been used. If the wound is a punctured one and cannot be cauterized properly, it should be laid open with a scalpel to allow proper treatment. A bite should not be sewed up. If sutures have been introduced before the patient appears for treatment they should be removed and cauterization should be performed. The method of preparing the Pasteur vaccine and the scheme and method of administering it, as followed in the health department's antirabic clinics, is briefly outlined. For ordinary bites nothing stronger than a three-day cord is used. For face bites and extensively deep wounds two-day cords are employed. If the patient has been bitten by a positively rabid animal it is a practice to advise him to return for a second series of injections after the expiration of six months. This will avoid those rare instances of death when the particular virus concerned has a prolonged incubation period. In the case of face bites or very extensive wounds the entire course of treatment should be repeated two weeks after the completion of the first. The general hygienic measures used in the treatment of the disease are given. In addition to this, mention has been made of many of the various methods of therapy—medicinal and otherwise—which have been experimentally employed in animals or used in human cases in an endeavor to find a specific. Unfortunately, nothing has as yet proved itself in the least reliable. The routine method of handling dog bite cases in New York City is outlined. Regan points out especially that publicity and the institution

of proper federal laws are essential for the eradication of the disease in this country. That this ideal condition is attainable, the experience of other nations has shown. Federal laws should regulate the importation of dogs, the compulsory impounding of all stray animals and the proper supervision of all licensed dogs. Among the important measures comprised in this supervision is the use of a proper muzzle for dogs in all public places under the penalty of destruction of the dog.

Radiotherapy. F. Bryant, Worcester.—p. 270.

Diet in Tuberculosis.—Clarke's paper consists largely of more or less fixed deductions from the observation of a moderate number of cases of tuberculosis. He gives a number of diet lists in full.

Diet in Tuberculosis.—Morgan believes that there is still a tendency to overfeed in the treatment of tuberculosis. He feels that lunches should not be served to the tuberculous adult patient, except as a special prescription for an unusual condition. In his experience, serving only three meals per day has given better results, both from the standpoint of the patient and the institution.

Postinfluenzal Tuberculosis.—From an observation of cases and a study of the literature Murphy concludes that epidemics of influenza are not followed by any measurable increase in the incidence of tuberculosis. In people with mild or arrested tuberculosis a higher incidence of influenza is evident than in those with the advanced type. In people with active tuberculosis a certain degree of immunity is produced by the constant presence of a low grade chronic inflammatory process of the respiratory tract, which protects them to some extent against a frank invasion of influenza. Cases of glandular tuberculosis, especially the cervical and tracheobronchial type occurring in children, show a very high incidence of influenza, but very few frank cases of pulmonary tuberculosis follow. Persons in the prime of life, apparently free from physical defects and previous history of illness, are more susceptible to influenza than others.

Multiple Tumors of Mouse Mammary: Are They Independent or Metastatic? A. Fischer, Bergen, Norway.—p. 325.

Primary Spontaneous Tumors of Testicle.—Among 19,000 mice dying natural deaths and examined postmortem, about one half of which were males, twenty-eight instances of primary tumor of the testicle were found by Slye and her associates. Most of these resembled in all essential features the tumors that arise in the testicle of man and other animals, consisting of cells closely resembling the epithelium of the seminiferous tubules, arranged in an alveolar structure. Despite great vascularity and a markedly atypical structure, no remote metastasis was observed, although in one case a series of six contiguous independent nodules was formed, and one case showed bilateral testicular tumors. Two of the growths seemed to be true spindle cell sarcomas, one arising at the site of a wound. Three of the typical "orchidoblastomas" also followed trauma. No evidence could be obtained that any of these tumors had arisen in a teratomatous growth, and no cases of teratoma have been observed. One case of polymorphous cell sarcoma of the seminal vesicle of a mouse is described, apparently the second case of a tumor of this organ reported in a lower animal. Two cases of primary spontaneous tumor of the testicle in dogs are described. With the exception of one sarcoma, all the twenty-eight neoplasms of the mouse testis occurred in the members of a single strain of mice and its hybrid derivatives, thus substantiating the statement that heredity influences the incidence of tumor development in different organs or tissues. This fact also probably explains the absence of any recorded cases of tumor of the testis in mice observed in other laboratories.

Cancer in Hainan, China.—This statistical study of cancer in Hainan made by Bereciovitz brings out the fact that cancer in Hainan is as much a disease of the early decades of life as of the later decades. Cancer of the penis and glands of the neck is unusually frequent. Cancer of the exposed surfaces of the body is very common. Cancer of the stomach and of the uterus is infrequent.

- *Demonstration that Spontaneously Liberated Epinephrin Can Exert an Action on Heart. G. N. Stewart and J. M. Rogoff, Cleveland.—p. 397.

Pancreatic Secretion and Bile Flow.—By employing proper methods Voegtlin and Myers say it is possible to obtain an extract from brewers' yeast which causes an increase in pancreatic secretion and bile flow when this extract is injected intravenously into dogs. Secretin solutions obtained from the duodenum of hogs by the methods described in this paper evidently contained a considerable amount of antineuritic vitamin, as shown by their power in relieving the paralytic symptoms of polynuritic pigeons. The chemical and physical properties of secretin and vitamin are similar if not identical. Both substances are found in the same fractions.

Irrigation of the Subarachnoid Space.—Weed and Wegeforth record experiments dealing with the irrigation of the meninges by physiologic sodium chlorid solution and by Ringer's solution. The results of washing out of the subarachnoid space by a bland solution, in the presence of an otherwise fatal infection, are presented in detail. The authors found that irrigations of the spinal and cerebral subarachnoid spaces are well tolerated by cats if the irrigating fluid is composed of sodium chlorid, potassium chlorid and calcium chlorid in proper proportions (modified Ringer's solution). If, however, the irrigation is done with isotonic solutions of sodium chlorid alone, various toxic effects become apparent. Many of these animals die during or immediately after the irrigation; if this immediate toxicity is survived, convulsive seizures and acute mania are almost invariable. Recovery from such attacks is frequent. Single irrigation of infected meningeal spaces with modified Ringer's solution has prolonged the life of the animals, as compared with controls. The period of survival in many cases has been doubled as a result of this washing out of the infected meninges. Multiple irrigations have not been attempted.

Effect of Subarachnoid Injections.—The toxicity of certain antiseptics within the meninges was tested by Wegeforth and Essick and the results are recorded in detail. Most of the chemical bodies employed possessed definite toxicity so that unless given in suitable dilution and amount, death of the animal would ensue. With chloramin and flavine, in addition to the initial toxicity, a secondary cause of death in from five to ten days was brought about through direct injury to the central nervous system. With injection of small amounts of a suitable dilution the animals remain apparently normal but all have shown at necropsy pathologic changes in the meninges. The lesion consists of a more or less complete obliteration of the meningeal (subdural and subarachnoid) spaces with serofibrinous exudate; in the more severe cases the nervous system becomes involved in a process of destruction by direct continuity from the meninges. The blocking off of the subarachnoid space was complete in only one case, as demonstrated by the subsequent injection of ink. It was not, however, sufficient for the localization of the infection. The subarachnoid injection of compound solution of cresol and potassium permanganate, in the presence of an otherwise fatal meningeal infection, did not prolong the life of the animal.

Anesthetic Efficiency of Benzyl Alcohol.—Sollmann found that benzyl alcohol is a fairly efficient anesthetic for intact mucous membranes, greatly surpassing procain; ranking about with alypin and betaucain, and somewhat weaker than holocain or cocain. Its action is not as lasting as that of cocain, and even 1 per cent. solutions produce considerable smarting. Commercial solutions in ampules appear to deteriorate somewhat, so that Sollmann considers it preferable to use freshly made solutions, when possible.

Output of Epinephrin from the Suprarenals.—Stewart and Rogoff have been unable to demonstrate any decided and constant effect of strophanthin on the epinephrin output.

Therefore, they believe that statements in the literature that the drug causes a marked augmentation of the output are based on the use of inadequate methods.

Action of Epinephrin on the Heart.—It was demonstrated by Stewart and Rogoff that the epinephrin passing into the blood stream from the suprarenals at the ordinary rate can exert a definite action on the heart. This was clearly shown by the marked effect produced on the cardiac irregularity evoked by strophanthin when the suprarenal blood was temporarily excluded from the circulation or allowed to enter it. Similar observations were made in a case of cardiac irregularity occurring in the absence of strophanthin. It was proved by the artificial administration of epinephrin that the constituent in the suprarenal blood responsible for the observed effects was epinephrin.

Pneumonia Complicated with Emphysema.—During an epidemic of influenza, followed by bronch-pneumonia, at Camp Hospital No. 12, subcutaneous emphysema of the face, neck and chest wall, and in a few cases of practically the entire body, was noted in thirteen cases. The areas of emphysematous tissue showed no gross change, and the gas which escaped had no odor, but had a tendency to aid combustion. In all cases air was found in the mediastinal tissue, pericardial fat, and in most cases in the interstitial tissue of the lung. Pleurisy was noted in a number of cases, usually of a plastic type. In other cases it was rather gelatinous, especially on intralobar surfaces. One case with empyema complication was found. The lungs usually showed an extensive involvement. A gram-positive bacillus was isolated from the blood in two cases prior to death, and in heart blood and gaseous tissue in four cases at necropsy. The organism was rather large; spores were present at one end of the bacillus. No capsule was demonstrable. It was acid fast. In a few old cultures it was noticed in diplos, but chains were never seen. Culturally it grew in deep stabs, never on the surface, and the more luxuriant growth was always in the bottom of the stab, with formation of gas and breaking up of mediums. In secondary cultures gas appeared after from forty-eight to seventy-two hours. While no definite grouping or classification of the organism is made, the authors feel that its morphologic and cultural characteristics tend to place it in the *B. welchii* group. Its mode of entrance probably was through the respiratory tract, the organisms reaching the consolidated areas of lung.

Favus in an Adult.—In the case cited by Wolf the application of strong antiparasitics in lotion or ointment form has had no effect in destroying the offending parasite. The disease yielded promptly to a single epulating dose of the roentgen ray.

Juvenile Diabetes.—Of the three cases reported by Horowitz the oldest patient was only 3 years of age, and the youngest slightly more than 2 years old. The cases show the value of institutional over home treatment. Two patients were treated in the hospital and improved very much more rapidly than did the patient who was treated at home. In each case there was a definite history of an intestinal toxemia preceding the onset of the disease.

Care of New-Born.—Huenckens has collected seventy cases of premature infants coming under his personal observation; of these fifty-eight developed definite signs of rickets. Of the twelve who did not develop rickets, three were under observation too short a time and four were two to three weeks premature, leaving only five definitely premature infants that did not develop rickets. Therefore, fifty-eight out of sixty-three, or 92 per cent., of premature and twin infants were found definitely rachitic. The time of occurrence is of great interest, because rickets usually does not begin before the sixth month. Of thirty-three cases seen for the first time at or before four months, twenty-seven, or 81 per cent., showed evidence of rickets at that time. It is, therefore, evident that in the treatment of the special form of rickets in premature infants the deficiency of calcium must be made up. Based on the experimental work of Schloss, Huenckens has been using tricalcium phosphate and cod liver oil with very good results.

Treatment of Human Beriberi with Autolyzed Yeast Extract.—About twenty cases of human beriberi were treated by Saleeby with autolyzed brewers' yeast extract. Adults were given from 150 to 40 c.c. three times a day. Children were given from 2 to 4 c.c. every three hours. Larger doses did not seem to give better results. No sign of poisoning was observed. Only acute and uncomplicated symptoms of beriberi were observed under treatment. Chronic nerve, muscular, or cardiac lesions were actually unaffected. All acute peripheral symptoms of neuritis were affected quickly. Marked results were noted in less than three days and a week's treatment seemed to give full relief in mild acute cases. Treatment was generally followed up for two weeks at least. Infantile beriberi symptoms were relieved with comparative rapidity. Edema yielded quickly, and nutrition improved at once. No special diet was prescribed. Patients were given regular hospital diets in accordance with the state of their digestion. Children receiving the extract continued to nurse at the mother's breast. The effect of the autolyzed yeast extract used is similar to that produced by the hydrolyzed extract of rice polishings; it seemed weaker, however.

Treatment of Typhoid Fever.—The treatment of ninety-eight cases of typhoid was carried out by Lantin under two general groups; namely, (a) treatment with foreign protein, which includes sensitized and nonsensitized vaccine, peptone and milk; (b) treatment with colloidal preparation, such as colloidal gold. On the basis of his experience, Lantin is inclined to believe that the nonspecific theory with regard to the action of vaccine as used in this investigation seems plausible, but that the exact details of the mechanism of

action of each kind of treatment administered is not yet fully understood. However, it was observed that a moderate reaction, following the administration of any of the treatments discussed, produced beneficial effects.

Autogenous Vaccines in Treatment of Chronic Nasal Catarrh.—The cases on which Mackey's paper is based concerned patients suffering from (1) recurrent acute nasal catarrh, (2) chronic nasal catarrh or (3) chronic postnasal catarrh. Mackey always uses an autogenous vaccine. The vaccines were made from the germ or germs which he believed to be responsible, and always from the primary cultures when these were pure. Mixed vaccines were made when two or more germs grew profusely on the plates, or when, as sometimes happened, a different infection was found in the two nasal passages. The vaccine most frequently used was pneumococcus, either pure or combined with some other germ, and the next on the list was Pfeiffer's influenza bacillus; then *M. catarrhalis*, *Staphylococcus aureus*, *Streptococcus mucosus*, *B. mucosus-capsulatus* (Friedlander's), and, last of all, *B. Septus* and *B. coryzae-segmentosus*. The vaccines were made in such strengths that 20 minims represented the maximum dose. Mackey began with 4 or 5 minims and gradually increased the dose, giving twelve doses at intervals of a week. The maximum dose of pneumococcus and streptococcus used was always 150 millions for an adult and for the other germs 300 or 400 millions. In one half the cases the catarrh was cured and the nasal passages were normally sterile. In about one third of the cases the catarrh persisted in a modified degree.

Renal Efficiency Tests in Nephritis.—Leathes states that respiratory activity can effect the reaction of the urine in a very marked degree as is shown by experiments in which the subject voluntarily increased the depth of his breathing for an hour or even half an hour at times when the reaction of the urine was otherwise certainly acid, for instance, in the late afternoon, or still more in the middle of the night. On every occasion in Leathes' experiments the results indicated a higher percentage of CO₂ in the lungs during sleep, and therefore give support to the hypothesis that the morning alkaline tide is related to variation in the activity of the respiratory center. The experiments are being continued.

- *Subordinate Causes of Pulmonary Hemorrhage. Yoshikawa.
*Urinary Analysis of Pregnant and Parturient Women. Mizutani.
Identification and Treatment of Ucinaria. Iritsawa.

Subordinate Causes of Pulmonary Hemorrhage.—From clinical observation Yoshikawa concludes that the following factors play an important part in the production of pulmonary hemorrhage: (1) Habitual drinking or blood relationship to a habitual drinker are very apt to be a part of the history in a case of pulmonary hemorrhage and it often is very severe; (2) a tall person suffers oftener from pulmonary hemorrhage than a short person; (3) the breast circumference does not influence the symptom; (4) the anesthetic thorax often produces the symptom; and also diffuse hardness produces a severe pulmonary hemorrhage; (5) males from 15 to 25 years of age and females from 25 to 35 years of age are especially prone to have pulmonary hemorrhage.

Results of Urinary Analysis of Pregnant and Parturient Women.—The author analyzed the urine of 100 women after parturition and of seventy-one pregnant women and found that albuminuria occurs after parturition in 84 per cent. Primiparas produced about 9 per cent. more cases of albuminuria than multiparas. Serious cases of albuminuria occur twice as often in primiparas as in multiparas. Serious cases of albuminuria are met with oftener among younger persons; they decrease in number as the age advances; 16 per cent. of the postparturient women had casts. The primiparas had casts twice as often as the multiparas. In 68 per cent. of cases of albuminuria at parturition the condition disappears on the second day, while in 85 per cent. it disappears within six days. Albuminuria that is associated with casts is more persistent than when no casts are present; 43 per cent. of these patients were unimproved on the sixth day. The percentage of improvement in postparturient albuminuria is antiproportional to the concentration of albumin at the time of the parturition. The multipara improves better than the primipara. Sugar was demonstrated in 3 per cent. of the parturient cases; in 5.6 per cent. of the postparturient cases sugar was present. A positive indican reaction was demonstrated in 13.3 per cent. of the parturient and 15.7 per cent. of the postparturient cases. A higher percentage of positive indican reactions was obtained in primiparas than in multiparas. A positive reaction was obtained in 18 per cent. of the parturients and 7 per cent. of the postparturients. Epithelial cells were demonstrated in 96 per cent. of the parturients and 98 per cent. of the postparturients. Leukocytes were demonstrated in 92 per cent. of the parturients and 96 per cent. of the postparturients. Erythrocytes were demonstrated in 12 per cent. of the parturients and 8.5 per cent. of the postparturients.

- *Intravenous Injections of Antimony Tartrate (Tartar Emetic) in Bilharziasis. F. E. Taylor.—p. 246.

Normal Vital Capacity in Man.—The results of Dreyer's investigations enabled him to establish definite relationships between vital capacity and body surface, body weight, stem length and chest measurement, and to show that vital capacity is not a simple function of height, as Hutchinson claimed. Vital capacity is a function of weight. Dreyer illustrates his investigations by many mathematical calculations.

Etiology of Influenza.—Examination by Beaumont of material obtained from patients suffering from influenza showed the presence of a mycotic organism. Beaumont suggests that it is possible that influenza is a mycosis, not necessarily in all cases a bronchomycosis, but perhaps in some an enteromycosis. Although the results obtained do not justify an assertion that influenza is a mycotic infection, the author states that they appear to demonstrate the fact that such an organism is present during the disease, and afford a means of unifying the seemingly discordant results that have been obtained by other workers.

Tuberculosis in Asylum Patients.—A study of the incidence of tuberculosis among asylum patients was made by Elkins and Thomson. They found that the mentally abnormal person is, generally speaking, more liable to develop tuberculosis than the individual who is mentally normal. This liability is primarily due to predisposition dependent on the mental condition. The determining factor is the spread of tuberculosis among the asylum patients in contact infection. Contact infection among the mentally abnormal is frequently due to infected excreta. In view of the extreme susceptibility on the part of asylum patients to develop tuberculosis the authors hold that it is essential that increased efforts should be made to provide such conditions of asylum life as will tend to counteract such susceptibility.

Antimony Tartrate in Bilharziasis.—Ten cases of vesical bilharziasis were treated by Taylor by Christopherson's method which consists in giving a course of injections of tartar emetic on alternate days for a period of from fifteen to thirty days, commencing with 0.5 grain dissolved in 6 c.c. of distilled water, and increasing by 0.5 grain up to 2 grains until a total of 30 grains has been injected.

Puerperal Infection: Its Relations to Polypoid Decidual Endometritis. Noyes is convinced that the great majority of cases of serious puerperal infection, fundamentally associated with the interior of the uterus, are due to polypoid decidual endometritis, with or without adherent placenta. The involved decidua may take the form of polypoid or of

papillomatous outgrowths especially over the placental site or it may merely be thickened and uneven, the particular type depending apparently on the extent and distribution of the interstitial fibrous tissue. The disease may or may not lead to abortion, the most pronounced cases being met with after full time labor. It is a frequent cause of adherent placenta. The great outstanding feature of the disease from a clinical standpoint is the singular liability of the diseased decidua to become infected and thus, perhaps, to lead to septicemia, thrombophlebitis, or other fatal effect. The microscope practically always gives evidence of this infection of the diseased decidua. The indications for treatment are clear; the diseased membrane should be removed promptly and thoroughly.

Diabetes Mellitus Treated According to Allen's Method.—Fitz and Bock report observations on a case of diabetes mellitus so treated. At entrance to hospital the patient had a blood sugar concentration of 0.58 per cent. and an acidosis sufficient to lower his alveolar CO₂ tension to 20 mm. During the first twenty-four hours in the hospital he excreted 116 gm. of glucose and 0.98 gm. of ammonia nitrogen. These facts show that the patient was critically ill. On the third day of a carbohydrate free diet the patient's urine showed D=N ratio of approximately 3.65=1, and afforded additional evidence that the case was one of maximum severity. The patient was treated according to the method proposed by Allen, and illustrates its value in a favorable case. A seven days' fast was necessary to render the patient's urine free from sugar. At the end of this period the blood sugar had fallen to 0.17 per cent., the alveolar CO₂ tension had risen to 44.8 mm., the ammonia nitrogen excretion had fallen to 1.37 gm., and the patient's condition was much improved. After the urine was sugar free, the carbohydrate tolerance was tested by a systematic daily increase in a pure carbohydrate diet as was possible to be obtained in the form of green vegetables. The patient tolerated 150 gm. of carbohydrate by this method without becoming glycosuric. During this time the blood sugar fell to normal and was not found materially increased on the last day of the test, when repeated bleedings were made to determine the degree of postabsorptive hyperglycemia. During the period of carbohydrate feeding, the alveolar CO₂ tension remained high, and the ammonia nitrogen excretion dropped to about 0.30 gm. in twenty-four hours, showing that all acidosis had disappeared. The carbohydrate sparing effect on protein metabolism was demonstrated. The nitrogen excretion dropped from about 19 gm. in twenty-four hours on the last day of the fast, to about 7.5 gm. when protein intake was low. As the vegetable protein intake increased considerably the urinary nitrogen increased somewhat. After thirty-three days observation the patient

was discharged from hospital in good condition with normal blood sugar concentration, with trivial acidosis, and approximately in nitrogen equilibrium on a mixed diet within his tolerance, yet ample for his bodily needs.

Lymphocytosis in Soldiers.—A continued clinical and hematologic examination of 438 soldiers, including controls, was made by McDougall; altogether 515 total white cell counts and 667 differential counts were done. Lymphocytosis during the apyrexial periods and polymorphonuclear leukocytosis during the pyrexial periods was the condition found in the regularly relapsing type of trench fever. Cases of regularly relapsing trench fever and of the influenzal type may merge gradually into the irregularly relapsing form. In the irregularly relapsing type there is no such definite fluctuation in the cells as is found in the regularly relapsing type. The existence of sustained lymphocytosis in the presence of a temperature swinging between 98 and 100 F., with symptoms of pain in the head, back and legs, especially in the shins, may be taken as typical of this form of trench fever. A normal differential blood count, in the absence of fever and subjective symptoms, McDougall holds may be regarded as proof of the absence of trench fever infections. A certain proportion of cases of irregularly relapsing trench fever show an excess of large mononuclear cells. These cases are accompanied by very intense shin pains. The influenzal type of trench fever is the mildest form of the disease. The total white cell count in the enteric type is moderately high. In addition, polymorphonuclear leukocytosis is present during the fever. These points serve as useful guides in the differential diagnosis from enteric infections. The vast majority of cases of D. A. H. following trench fever show lymphocytosis, but this is present before the onset of the D. A. H. Temporary accelerations of the pulse rate when the patient is at rest in bed, and especially when he is afebrile, are evidence of a predisposition on the part of the heart for involvement in a more permanent instability. Trench fever can be separated from malaria and influenza by repeated blood examinations.

Respiratory Metabolism in Prolonged Undernutrition.—Poulton and Kyffel claim that the resting metabolism is considerably diminished in prolonged underfeeding, in fact, it may be as low as in complete starvation. The metabolism, measured in the erect position, in a state of muscular relaxation is also diminished. The pulse is slow. In prolonged underfeeding there is no increased efficiency during muscular work, as measured by the rate of increase in the respiratory exchange at different rates of walking. The heat output during muscular exercise is influenced by the deep and surface temperature of the body.

Effects of War Nephritis on Kidney Function.—The investigation on nephritic cases reported on by MacLean and De Wesslow disclosed that the presence of albumin in the urine or the extent of the albuminuria is of little value as an index to the gravity of the case, for it is well known that the more serious cases may show but traces of albuminuria. In general, the amount of protein in the urine in subacute and chronic cases is probably of more importance in indicating the predominating type of disease present than in furnishing information as to the gravity of the renal condition. In the early stages of an acute attack of nephritis the blood urea content furnishes the best indication of the state of the kidney. If this is normal, it may be taken for granted that the damage to the kidney is not sufficient to interfere with its normal function of excreting nitrogenous products. If, on the other hand, the blood urea figure is high, the most valuable information as to the progress of the disease is obtained by occasional estimations of blood urea. If the urea tends to get less, the prognosis is good; if it gets persistently higher, the outlook is correspondingly bad. In severe chronic interstitial conditions the same state of affairs is present. In many subacute and chronic conditions the kidney is not sufficiently damaged to cause an increase in blood urea, and so no information is to be obtained by this test. In such cases other means must be employed, and the authors found that the capacity of the kidneys to concentrate urea in the urine, under conditions described, affords, very helpful information

If after receiving 15 gm. of urea by mouth, the patient excretes urine containing about 2 per cent of urea, it is safe to conclude that the kidney is at least fairly efficient. If the urine concentration is low, it is in the great majority of cases an indication that the kidney is inefficient. Finally, the authors regard it as most important to emphasize that, whatever the result of the various functional tests may be, no prognosis should be given without first carefully examining the state of the cardiovascular system.

Fatal Cases of Pernicious Malaria with Massing of Plasmodia in Cerebral Capillaries.—Twenty-one patients dying in coma showed massing of numerous malarial parasites in the cerebral capillaries. Every patient was energetically treated with quinin either by the intramuscular or intravenous routes, usually both, from the time of first coming under medical observation. The onset of such cerebral symptoms as drowsiness, mild delirium, apathy, restlessness, was noted as gradual in twelve. Of the remainder, nine, when first seen, were already deeply comatose, and no other history was available. In these Dudgeon and Clarke venture to assume it is at least probable that the onset of coma was sudden or that it deepened rapidly. Usually, the notes indicate a gradual progression from mild to deep coma. In twelve cases from the onset of the first important cerebral symptom, the end was fatal in twenty-four hours or less. The most rapid termination was six hours (one case) and the longest duration sixty hours (two cases). The temperature, where such record exists, was raised invariably from 100 to 105 F. The capillaries, and in the most severe cases the arterioles, were engorged with numerous infected red blood cells which showed the well known tendency to collect at the periphery of the vessels, free parasites, melanin particles, prominent and detached endothelial cells. Various phases of development were represented, "dot" forms, fine rings, segmenting forms, but crescents were not seen. All gradations of blocking up to complete thrombosis with agglutination of and altered staining reactions of the corpuscles were exemplified. Small hemorrhages around the smaller blood vessels were seen in six cases. In one instance the rupture of vessels had allowed the discharge of parasites into the tissues. In most instances examined the rupture of the cerebral capillaries or capillaries in other viscera had not led to the discharge of parasites into the tissues. Abundant infected red cells were seen filling the vessels or tightly packed toward the vessel walls, while absence of infected red cells in the hemorrhagic zone was the rule, not the exception. Pigment, varying in amount, was present in the lining endothelial cells, in detached phagocytes and free in the lumen. Nerve cell degeneration was observed in eleven cases, as shown by cells of abnormal size and shape, loss of Nissl granules, eccentricity and distortion of nucleus to its complete disappearance. The spinal cord in one case showed advanced cell degeneration of the anterior corned cells with the typical vascular changes and complete blocking of vessels. This patient had developed paraplegic symptoms before death. Local accumulations were found most often in the spleen, marrow, heart and pancreas; less frequently in the intestines, lungs and suprarenals; occasionally in the liver, kidney and thyroid. Fatty and other degenerations of the cardiac muscle, acute tubal "nephritis," vascular changes in the suprarenals, terminating in tissue necrosis and all varieties of pulmonary congestion and hemorrhage were recorded.

Pigmentation of Oral Mucous Membrane.—Wetzel calls attention to a certain group of cases in which pigmentation, not connected with Addison's disease, occurs in the mucous membrane of the mouth. The pigmentation is in the form of blackish spots and patches on the mucous membrane of the lips or cheeks and sometimes of other parts of the mouth. It is associated with pigmentation of the skin of the face, especially about the mouth and possibly (in one or two cases) of other parts of the body. It occurs in persons of dark complexion, perhaps especially in Rumanian Jews and in certain races, such as Lascars. It is of unknown causation and seems in some cases to be of "physiologic" or, perhaps, atavistic origin. It may be analogous to the black patches often present in the oral mucous membrane of dogs and other

animals. It appears to be allied to simple pigment nevi of the skin, on the one hand, and to freckles (ephelides, lentiginosae) on the other hand. Weber suggests the possibility that a similar kind of pigmentation may be connected in some indirect way causally with pernicious anemia.

Heart Block and Bradycardia Following Influenza.—In cases of simple influenza, and in many cases with pulmonary complications, bradycardia was extremely common during the epidemic of 1918 and 1919, in which many hundreds of cases were admitted to the Royal Navy Hospital, Haslar. In the majority of cases, after the temperature had become normal, the pulse rate quickly fell below 60 and remained between 50 and 60 for a variable number of days. In more extreme cases a pulse rate of from 36 to 48 was noted. Cockayne took notes of 132 cases in which the pulse fell below 50. Polygrams were taken in fifty-five cases; in nineteen the bradycardia was due to a condition of partial heart block. In some of the remaining cases heart block may have been present, but was not proved. The cases of heart block are divided into sinus block, prolongation of the *a-v* interval, 2:1 and 3:1 heart block. No case of complete heart block was met. The points brought out by these cases are that the majority of cases occurred in young men and that all had pneumonia. The pneumonia in most of them was very mild, and in none really severe. All the patients were kept in bed until some days after heart block had disappeared, and when they were examined a month or six weeks later only one complained of any cardiac symptoms (precordial pain and giddiness). None showed any undue irritability of the heart.

nitz and L. Corral.—p. 150.

Malarial Pleurisy and Peritonitis.—Cordier is inclined to accept a direct action by the malaria parasite on the peritoneal and pleural serous membranes. Cases of malarial mammitis have been published recently, confirming the possibility of a direct action by the parasite on the tissues. He describes four cases typical of the pleural and peritoneal reactions. It may be acute in both pleura and peritoneum, with double effusion developing within a few hours, the intensity of the abdominal phenomena suggesting peritonitis from perforation. The pleurisy disappears without leaving scars. In another group there may be a peritoneal reaction without effusion but entailing meteorism, biccough, vomiting and symptoms suggesting peripneumonia or gallbladder complication. In another group the pleura seems to bear the brunt of the attack; two of the cases described presented this pure form. The effusion abounded in reds with almost pathomonocytosis, and eosinophilia not above 8 per cent. He never succeeded in demonstrating the malaria parasites in the effusions.

Undulant Fever in Tuberculosis.—Béraud warns that the only way to obtain a constructive record of the temperature in the tuberculous is to record it at least four times a day, at 8, 2, 6, and 10 a.m., and together the figures for the different periods in a given day. He found this in hundreds of cases of the fever of tuberculosis. He carried a special watchlike temperature record, and observed a similar course of the temperature, with a wide range in ten patients. Study of his cases seemed to indicate this undulating type of temperature curve as a typical, typical, serous form of the infection, with the exception of the local processes and a few cases, serous, in which the local lesions. In the temperature record, the fever varied from 38, 39, 40, or 41, or even 42, in the 24-hour periods as a whole, and all cases of these periods, from three to fifteen in number, the undulating temperature within the so-called pleural reaction corresponded to a much more pronounced fever. It was obtained, hard to be convinced, by means of clinical observation, and particularly thermos-

and chronic. Tuberculin offers the best prospects in treatment in the milder forms of this undulant temperature course.

Hygiene of Aviation.—Ferry exclaims that aviation brings us surprise after surprise. His own supervision of aviation during the war has revealed many unexpected pathologic phenomena, especially the changes in the kidneys, their sluggish functioning and the resulting auto-intoxication. The men complained of general and nervous asthenia, irritability, nightmares, etc., and sometimes of pain in the lumbar region. One officer had certain symptoms of Bright's disease, with dizziness, on the ground and sometimes on a flight when he was fatigued or had indigestion. Restriction to milk for four or five days and 0.5 gm. of theobromin twice a day the first week generally corrected conditions in such cases except when there were symptoms of weak heart. In this case the prolonged asthenia seemed to be due to suprarenal insufficiency, and it yielded to epinephrin under which also the often concomitant bradycardia disappeared likewise. Personal experiences in a pneumatic chamber with low atmospheric pressure confirmed the injury of the kidneys, and the necessity for care in the diet to ward off further damage. Protection against the cold should include the exposed part of the face; it should be protected with a salve or cream.

The Immunizing Power of the Serum of Diphtheria Bacilli Carriers.—Lévy and de Lollardy have now a record of eight carriers whose serum has immunizing power. Two of them had never exhibited any clinical reaction to the infection.

Archives des Maladies de l'App. Digestif, Paris

*Simple and Rapid Test for Acids of Gastric Juice. M. E. Binet

and G. Verpy.—p. 112.

*Megacosophagus. L. Bard.—p. 116.

False Cancers of the Stomach.—Lion refers to the tumors found in the stomach at operation and so extensive that their removal seems out of the question, and yet these patients with supposedly inoperable cancer keep on living and finally seem to throw off the disease. He describes a striking case of the kind in a man of 30 who had been having stomach disturbances for ten months with finally signs of stenosis of the pylorus. The operation showed a tumor at the pylorus extending to the lesser curvature and surrounded by hypertrophied glands so numerous and some at such a distance that any operation seemed hopeless, although the tumor was movable in its entire extent. The tumor was left unremoved after the gastro-enterostomy, and the man rapidly regained his health. He had refused the proposed treatment as for syphilis, and he lived in good health for twelve years when he succumbed to intercurrent disease. The stomach was found small but with no tumor nor scars nor pronounced thickening of the walls. The pylorus was retracted, but the gastro-enterostomy opening was perfect, and the glands were of normal size. In a second case the man of 57 with an actual, inoperable gastric cancer survived for four years and seven months after the palliative gastro-enterostomy. Re-examination of 76 other cases of palliative gastro-enterostomy for inoperable cancer showed that one patient survived for fourteen years; 4 for nine; 2 for eight; 3 for seven; 6 for six; 9 for five; 13 for four; and 38 for three years. In 5 of these cases the malignant nature of the tumor was established beyond question, and these survived from three to five years. In one other case of actual cancer, the patient survived the gastro-enterostomy for two years and four months. Lion discusses the various affects that may be mistaken for cancer, especially ulcer, syphilis and tuberculosis. Even with the stomach open before him, the surgeon may be unable to tell certain inflammatory from malignant lesions. In case of doubt, histologic examination of a gland is advisable. Lion's experience with 200 cases of unmistakable cancer, on the other hand, demonstrates the great corroborative value of the chemical stomach findings. Syphilis simulates gastric cancer most often; the benefit from treatment is the touchstone. But in one case described there was associated gastric cancer and syphilis, and the umbilicus also ulcerated. Under specific treatment this healed and the tumor in the stomach

metled away, but when a complete cure seemed impending, the incipient cancer made its presence felt.

Determination of Acids in Gastric Juice.—Binet and Verpy describe a technic which is based on Gautier's simplification of Robin's modification of Topfer's method. They commend the simplicity and the rapidity of the technic. It shows by three changes of tint in the one specimen of gastric juice in the single tube the content in the gastric juice of the hydrochloric acid, of the acids of fermentation, and of the total acidity. This is accomplished by adding a 0.548 per cent. solution of soda (137 c.c. of normal sodium hydroxide with water to 1 liter). The tube of 1.5 cm. caliber is graduated in tenths of cubic centimeters to a height of 15 c.c. above the first mark, which represents a capacity of 5 c.c. Two other reagents are required: a 2 per cent. alcoholic solution of phenolphthalein, and Topfer's reagent, which is a 0.5 per cent. alcoholic solution of dimethylamidoazobenzol. The filtered gastric juice is poured into the tube to the 5 c.c. mark; then one drop of the phenolphthalein solution and one drop of the Topfer. If there is free hydrochloric acid present, the fluid turns a cherry red. Then with a dropper the titrated solution of soda is added, agitating at each drop, until the fluid turns the color of mandarin orange juice. This indicates saturation of the HCl and the figure marked on the tube represents the weight of free HCl in a liter of gastric juice. The soda solution is added further, drop by drop, until the tint veers to a distinct yellow. The figure representing the free HCl is then subtracted from the figure reached now by the fluid, and the difference represents the acids of fermentation present. The soda solution is then added further, drop by drop, until the tint turns slightly pinkish. The mark then reached represents the total acidity. By subtracting from this figure the sum of the two other figures, we get the figure for the HCl in organic combinations. Comparative tests with this technic have confirmed its reliability, and it is in constant use in Loeper's service.

Mega-Esophagus.—Bard here reports two cases of abnormally large esophagus which confirmed his previous publications on mega-esophagus, and especially the peculiar shape assumed by the sagging lower end, which is seen to curve off toward the left in the roentgenogram. All these patients found spontaneously that they could swallow better standing up, and also that a deep inspiration aided in the passage of the swallowed food into the stomach by the traction from the diaphragm.

*Extrasystole under Strophanthin. C. Landry and M. Lecomte—p. 211.

*Nervous Complications in Leukemia. J. Tapie and A. Cassar—p. 218.

Extrasystole from Nervous Lesion.—In the case described by Heitz, the war wound had injured vessels and nerves in the left side of the neck. Extrasystoles were numerous and there was dyspnea on effort, with paralysis of the vocal cord.

Strophanthin and Coupled Rhythm.—Simici relates that the coupled rhythm with pseudobradycardia developed after intravenous injections of strophanthin in a man of 48. Such cases testify to a cumulative action by strophanthin, similar to what has been observed with digitalis. The best means to combat arrhythmia of this kind is with epinephrin. Almost simultaneously Roumier in France, Housay in Argentina and Danielopol in Roumania called attention to the efficacy of epinephrin in arresting heart block. In the case reported, the coupled rhythm and the bradycardia of the radial pulse completely subsided after the third subcutaneous injection of epinephrin, 1.5 mg. fractioned, in twenty-four hours.

Myeloid Leukemia with Hemiplegia or Herpes Zoster.—Tapie and Cassar add two cases to the list of those in which nervous affections developed as complications of leukemia. They took the form of cerebral hemorrhage, convulsions, facial paralysis, or symptoms from pressure on nerves by lymphomas, etc., and in their own cases, occipitofacial herpes zoster in the man of 57, and complete hemiplegia in the other, a younger man with rapidly fatal leukemia.

Trench Foot (3,000 cases of froids des pieds). R. Mercier—p. 80.

*Focal Auscultation. O. Peyret—p. 83.

Effects on the Organism of Centrifugal Force.—Broca and Garsaux found in a fatal case that death had occurred from anemia of the brain, lungs and heart muscle, aided perhaps by pressure on the solar plexus, and yet the abdomen was nearer the revolving axis. As long as the heart continues to receive blood, it sends it into the abdominal vessels. Experimental research on dogs confirmed the necropsy findings in this case, and emphasized the probable advantages of aviators' wearing an abdominal band.

Spinal Anesthesia.—Le Fillatre reviews his experience with 194 cases at Paris in which he applied spinal anesthesia by what he calls *barbotage arachnoïdien* (described in these columns, Sept. 14, 1918, p. 932). The results were perfect, he says, and as soon as the patients were returned to their bed they felt so well that some asked for their correspondence or wanted to smoke. In the Macedonian campaign he operated with it on 800 wounded too badly injured to be evacuated, and notwithstanding their malaria and losses of blood the results surpassed all anticipations. In another series of 1,769 severely wounded, coming directly from the Chemin des Dames battles, the mortality was scarcely 0.5 per cent. In civilian practice, surgery of the abdomen, thorax, head and neck is rendered not only easier but more certain with this method of anesthesia. It is free from postoperative surprises; the patient is not intoxicated with general anesthesia; the physiologic functioning of the red corpuscles, the kidneys and the liver is unimpaired, and the recuperation after the operation proceeds more smoothly and more rapidly. The anesthesia of the head, arms, chest and abdomen was absolute in every instance, and persisted from three quarters of an hour to an hour or more for the head and neck, to two hours and more for the legs. There never was any vomiting, headache or paralysis, and the slow return of sensibility (about eight hours) renders morphin unnecessary. The only by-effects observed were in about 2 per cent. a very slight disturbance in respiration, with small pulse and slight pallor, never lasting more than five or ten minutes at most, and never alarming.

Focal Auscultation.—Peyret recalls that sound waves are reflected back from an obstacle like light waves, the angle of reflection equal to the angle of incidence. Hence in certain conditions they converge toward the same spot. At certain points, therefore, several waves meet, and the sound therefore is louder at these points, or louder as he calls them. If, for example, a round table is percussed, the point of greatest resonance will be at the center, which is the focus where the sound waves meet. He gives diagrams showing the application of these principles in auscultation of the chest, calling attention to the points where the sound waves converge, and the lines along which there is most convergence, explaining the physical and geometrical laws governing the findings. The ear at the one focal point can hear the percussion sounds from different regions, even from the top apices. The findings are exceptionally instructive under these conditions with incipient pulmonary tuberculosis, he has determined in examining thousands of military recruits, suspects in the army. The method is likewise instructive for the heart, abdomen and limbs.

Bulletins de la Société Médicale des Hôpitaux, Paris

June 20, 1919, 43, No. 21

*Primary Splenomegaly. G. Lemaire—p. 599.
*Azotemia in Acute Infections. P. Merklen and C. Kudelski—p. 604

Primary Splenomegaly.—Lemaire relates that no germs could be cultivated from the blood in the case of primary splenomegaly reported, fatal in five months, but monkeys inoculated with scraps from the spleen developed a similar febrile and fatal disease, with the same changes in the blood, anemia, leukopeny and mononucleosis.

Azotemia in Acute Infections.—Merklen and Kudelski admit that although progressive acute azotemia is a grave sign in acute infectious diseases, the converse is not necessarily true. The subsidence of the azotemia is not always a sign of approaching recovery. The oliguria may be a factor in the azotemia in acute infectious diseases but the principal factor is the exaggerated dissimilation, and this is the side on which danger lies. A single determination of the degree of azotemia is not instructive, but if the curve keeps high or rises, the prognosis grows graver.

*War Neuroses in Serbians. D. A. Hesiard—p. 259.
*Serologic Tests in Dysentery. E. Dubot and R. Damade—p. 265.
*Intensive Treatment of Syphilis. H. S. Morin—p. 268.
*Unilateral Mydriasis. Cabannes—p. 270.

War Neuroses.—Hesiard comments on the extraordinary number of cases of functional motor disturbances in the legs among the soldiers in the Serbian army. Among 500 cases of functional nervous disturbances in his service in Serbia, 115 were of this type of incoordination and tremor in the legs. This tremulous astasia-abasia amounted to actual paraplegia in some cases. Combined physiotherapy and psychotherapy proved successful finally in every case.

Serodiagnosis of Dysentery.—Dubot and Damade call attention to the specific nature of the sensitizer with dysentery serum, the Shiga serum responding only to Shiga antigens and not to Flexner. There may be sensitizers, but the action is much more pronounced with the specific antigen. Tests with serum from forty-eight nondysenteric subjects were constantly negative.

Unilateral Mydriasis.—Cabannes explains that mydriasis may be the result of paralysis of the sphincter or it may be from the mottiness of the retina. These two conditions can be differentiated with unilateral mydriasis by the fact that the pupil of the nonmydriatic eye contracts in a bright light if the eye in mydriasis has good perception of light. The crossed reflex contracts the pupil of the other eye. When there is no miosis on direct exposure to a bright light, then there is no crossed reflex and this demonstrates that vision is lost in the eye in mydriasis.

Measuring the Mass of the Blood.—Javal and Boyet review the different methods in vogue for estimating the mass of the blood, its various distribution, and the ratio between the plasma and the corpuscles. Nearly ten pages are devoted to this study, and at the end of it they affirm in conclusion that the same blood treated with the same solution of a neutral salt gives always the same ball of corpuscles after centrifugation. These corpuscles which do not involve sedimentation seem to be more exact. In health, the corpuscles in human blood have nearly half of the total volume of the blood. The erythrocytometer is particularly useful in hydremia for a series of examinations of the blood in the same patient.

Bentben in Spain. Reviewed when published elsewhere (June 5, 1918, p. 1893).

Pseudarthrosis of the Hip.—De Labrousse has found it possible to detect pseudarthrosis of the hip after fracture by raising the reclining patients the feet together and again

with the pathologic thigh in forcible abduction but the tube and conditions exactly the same otherwise. The roentgenograms then will show either that the proportions between the parts of the upper end of the femur have remained the same and the head has simply revolved in its cavity; or else the head has scarcely moved while the relations between the other parts have altered. He calls this the abduction sign, and has found it a reliable means to reveal the pseudarthrosis.

*Fatigue, Especially in Aviators. M. Sistrion—p. 61.
*Hydrotherapy. R. Ledent—p. 65.
*Diagnostic Importance of Chemistry of the Stomach. L. Pron—p. 70.
*Transfusion of Blood in Shock. R. Ducastaing—p. 73.

Gastric Chemistry.—Pron does not attach much importance to the stomach chemistry after a test meal, but he regards the analysis of the contents of the fasting stomach in the morning as of primordial importance. Nothing else in this line approaches it in pathologic significance. Continuous hypersecretion, acid catarrh, is common, and any person having regularly in his fasting stomach up to 200 c.c. of a highly acid fluid must be regarded as seriously affected, even although there may be no symptoms from it at the time. Among 388 patients with a splashing sound in the fasting stomach, he found hydrochloric acid in 247 and liquid acid without free acid in seventy-three. The lack of concordance between such findings and the subjective condition is a daily source of error. Because the nervous system happens to become less sensitive, so that the patient suffers less or gains in weight, is no reason for assuming that the stomach conditions have returned to normal or that the trouble is merely "nervous."

Presse Médicale, Paris

*Pneumography Applied to Cardiography. C. Loubry and A. Mongeot—p. 393.
*Treatment of Hallux Valgus. E. Juvara—p. 395.
*Dressure in Treatment of High Blood Pressure. Carron de la Carrière—p. 397.
*Technic for Combined Treatment of Syphilis. L. Bory—p. 399.

Pneumography Applied to Cardiography.—Loubry and Mongeot have been applying to the study of the heart an adaptation of the pneumatic cuff, and they here describe the findings in research of this kind. Comparison of large numbers has shown among other things that the periodic modifications of the amplitude of the pulse, the reflection of the variations in the differential pressure, are often influenced by the respiration but frequently in an opposite direction. He explains this in detail, emphasizing the numerous factors involved and the polymorphism of the variations in the respiratory amplitude.

Hallux Valgus.—Juvara reiterates that in order to correct hallux valgus it is necessary to shorten the overlong metatarsal bone. When this is of proper length, the other bones slip back into their normal place. He cuts a slanting wedge-shaped piece, with a broad tip, out of the metatarsal bone, and drives in a nail to hold the slanting stumps together after throwing a ligature around them. The exuberant capsule is cut down to normal proportions, and as the toe resumes its normal shape the ligaments are no longer stretched unduly. He has operated with this technic in five cases with perfect results. He worked out this technic on the cadaver when he was called on to operate in a case in which two operations by other methods had failed to relieve.

Spa Treatment of High Blood Pressure.—De la Carrière expatiates on the advantages in appropriate cases of physiologically stimulating urinary functioning by systematic ingestion of a weak mineral water. This form of physiotherapy may benefit the entire system by washing out retained chlorides and other toxins, and thus arresting any toxic spasm of arteries and relieving the heart. When the high blood pressure is of functional origin, spa treatment may do wonders. With organic high pressure, fine results may also be attained if the permeability of the kidneys is retained. This can be most readily ascertained by the test of induced diuresis, or experimental polyuria, that is, the test elimination of urine during the two hours after drinking a given

amount of water, fasting, and reclining. A considerably larger proportion of night urine is also instructive. When these tests give negative findings, spa treatment may help materially and serious clinical symptoms may melt away. Another useful test is by comparing the output of urine with the differential blood pressure. Dividing the figure representing the total twenty-four hour urine (in liters) by the figure representing the differential arterial pressure (in cubic centimeters by the Pachon oscilometer), the quotient represents the daily output of urine per cubic centimeter of differential pressure. In normal conditions this quotient is 0.25 or above; with sclerosis it is 0.20 or below, and organic mischief is certain.

Influenza and Surgery. J. L. Faure.—p. 405.

*Hour Glass Stomach. V. Panchet.—p. 405.

Influenza Noma. G. Portmann.—p. 407.

Hour-Glass Stomach.—Panchet has operated in twenty-one cases of hour-glass stomach. The best results were obtained with extensive resection; in two cases he had to do a second operation as the first had been too conservative. Regional or spinal anesthesia was exclusively used. Five types of complications were observed, stenosis of the duodenum accompanying the bilocular constriction; ulceration with the latter involving the abdominal wall, liver or pancreas; cancerous degeneration; perigastric abscess; a fistula into the colon corresponding to the constricted point; volvulus of the pylorus portion closing the lumen of the mediogastric orifice completely, and acute obstruction of the mediogastric orifice. The bilocular deformity is the result of the healing of a gastric ulcer or, more often, of a callous ulcer in full evolution. Treatment as for syphilis may be tried, if the general health is good, but if there has been much loss of flesh it is better not to wait for this. Persons with chronic ulcer generally lead an ordinary life, and are merely considered to be dyspeptic, nervous or neurasthenic.

Spi. Treatment of Gynecologic Affections. Mantez.—p. 276.

Solution of Sugar plus Lactic Acid in Local Treatment of Septic Wounds. B. Gheza.—p. 278.

The Oculocardiac Reflex in Mumps.—Margatot discovered that the oculocardiac reflex was exaggerated in eight ninths of about forty-five cases of mumps in soldiers. In several the heart beat slowed up at once by from twelve to twenty-eight beats and by the next day or two the pulse was much slower, declining from 100 to 52 in one case with orchitis, and from 120 to 68 in a case with tonsillitis. The blood pressure also declined to correspond. These and other data presented seem to demonstrate that vagotomy is habitual in mumps. Sympatheticotomy was exceptionally observed, and only when the pancreas was involved in the mumps. It corresponded then to the set of sympathetic phenomena noted with acute inflammations of the pancreas.

*Lethargic Encephalitis. A. Cramer.—p. 197; A. Répond. p. 249.

History of the Société vaudoise de Médecine from 1829 to Date. A.

Guisan.—p. 211. Com'd in No. 4, p. 149.

*Pathogenesis of Round Ulcer in Stomach and Duodenum. M. Bourcart.—p. 223.

Lethargic Encephalitis.—Cramer reports three cases of this disease, the first encountered at Geneva, and all developing early this year in previously healthy adults. Two of the patients recovered, but one still presents considerable laziness in his mental processes, and the other still has attacks of nystagmus and there is insomnia. Répond reports a case of recovery after nearly two months in the hospital during which iodid treatment was pushed.

Pathogenesis of Gastric and Duodenal Ulcer.—Bourcart has been seeking for features common to all patients with a tendency to round ulcer in stomach or duodenum, and has found that they are all characterized by more or less sagging viscera and flabby muscles. Whatever the primal cause, the result is a loss of normal abdominal balance, and the circulation of the nerves suffer. Vagotomy or sympatheticotomy is generally present. The lower part of the chest scarcely shares at all in the breathing movements, and he shows with nine illustrations how the ptosis, the faulty attitude and the shallow breathing combine to hamper the circulation still further. Treatment should aim to improve the respiration and circulation in the trunk, by deep breathing, expanding the lower ribs, drawing up the abdominal muscles, erect and reclining, and massage of the abdomen by the physician to restore the viscera to place and maintain them there, and vibratory massage below the liver to stimulate the circulation through it, supplemented by physical exercise and proper diet. His experience with treatment based on the above premises has given excellent results. The tendency to hematemesis subsided, the ulcers healed, and the pain and gastric functioning showed great improvement. All the digestive secretions show great improvement as the static condition of the abdomen returns to normal. "With a liver that breathes right," he adds, "the stomach does not bleed."

Gazzetta degli Ospedali e delle Cliniche, Milan

June 22, 1919, 40, No. 50

*Pellagra. A. Zilocchi.—p. 510.

Pellagra.—Zilocchi is chief of an insane asylum in a pellagra zone in Italy, and he has made a special study of the disease in this region and of adjoining regions where it does not prevail. His conclusions from his research sustain the general view that pellagra is the result of a too one-sided diet, not supplying enough calories, while the fact that it is usually poorly cooked favors gastro-intestinal derangement. The lack of proper nourishment in time induces a constitutional substandard condition, and the vegetative system suffers with all that this implies for the nervous and digestive systems and the skin. There is also secondary action from retained toxic waste.

*Azotemia in Infectious Jaundice. L. Dozzi.—p. 520.

July 3, 1919, 40, No. 53

Displacement of Heart. G. Binetti.—p. 531.

Nitrogen Metabolism in Infectious Jaundice.—Dozzi recalls that slight azotemia is almost constant in infectious jaundice, but in the mild cases it gradually disappears. In the severer cases, with restricted or suppressed diuresis, the azotemia grows more and more pronounced, and may induce symptoms of actual uremia, miosis, Cheyne-Stokes rhythm, etc. Instead of devoting all our attention to the jaundice in this disease, we must realize that the kidneys are involved and other tissues, and that it is not merely a disease of the liver. It is a general infectious disease, with multiple and extensive involvement. The treatment benefits by this conception. It is important to refrain from nitrogenous substances during the entire period when the tissues are finding it so hard to eliminate the nitrogen liberated by the tissues. It is important, further, to give albuminoids freely during convalescence to aid in the processes of repair, to replace the living substance destroyed by the disease.

*Desiccated Proteins X Antigen for Diagnosis of Typhoid. E. Siegel.

Id.—p. 549.

Vaccination Against Tuberculosis.—Maragliano here brings down to date his report on the vaccination of children and others against tuberculosis, which he has been advocating for

twenty-five years, as repeatedly mentioned in these columns. He aims to produce a minute focus by subcutaneous injection of dead tubercle bacilli, theorizing that in this focus antigens will be produced and that they will pass into the circulation from this focus, thus slowly and progressively inducing the production in the body of immunizing materials. His clinical and biologic tests have demonstrated that this production of antibodies does actually occur. Research now under way with Sivori's modification of the fixation reaction test has shown an appreciable reaction in healthy persons in two weeks after the vaccination: First the antigens show up more and more while the antibodies are scanty; then the antibodies become more and more evident by the end of one and two months, and they become very pronounced by the end of the third month. Then the antibodies show an ascending curve while the antigen curve keeps low. By the end of the fourth month the two curves run parallel for two months and then the antigen curve descends strikingly while the antibody curve persists nearly the same in its later course. The same results were obtained in monkeys and cows as in man, and five monkeys thus vaccinated were injected at the fifth month with one-tenth mg. of living bacilli, and all survived. Four died of the five controls, within five months. All these findings harmonize with those obtained by study of the agglutinating and opsonic power after the vaccination. The findings were likewise positive in infants born from women that had been vaccinated in this way during the pregnancy. Similar response to the tests were obtained by Levi at Parma; he determined the presence of antigens and antibodies in the blood of mother and fetus, in the placenta and in the milk.

The vaccination was applied to 3,702 members of families with tuberculosis between 1907 and 1914. The later history of 1,893 is known to date, 1915; of this number 1,819 were living and sixty-three had died from other than tuberculous processes and only eleven had died from tuberculosis. All those vaccinated in 1907 were found to be in good health to date. In twenty-six among the earliest vaccinated recently reexamined by a naval medical officer, all were in robust health, while the deviation of complement test revealed persistence of immune principles with predominance of antibodies. A number of persons have been vaccinated elsewhere and in other countries but Maragliano does not include these in his statistics. No inconveniences from the vaccination were ever observed, but the question whether the persons vaccinated might have escaped tuberculosis without this extraneous aid can be answered only by application of the method on a larger scale. At present, man can defend himself against tuberculosis only by acquiring a specific resistance against the bacillus which, notwithstanding all the measures of social prophylaxis, is bound to get to him. In this, Maragliano declares that his research, that is, Italy, has led the way.

Desiccated Bacteria for Biologic Tests.—Signorelli has in his institute has demonstrated that the nitrogen waste in the blood and the proportion of its various elements may fluctuate within wide limits from conditions in nitrogen metabolism altogether independent of the kidneys.

Blood Diseases. Maragliano comments on the new field for research opened by Ghedin's method of studying blood diseases by examination of a scrap of bone marrow obtained by biopsy. Ghedin has also succeeded in producing hyperglobulia in animals.

Desiccated Bacteria for Biologic Tests.—Signorelli has applied to *Proctus X 19* the method of making durable antigens devised by Micheli and Satta. It has proved very efficient, and he commends this technique in high terms. The suspension of the bacteria is desiccated in a vacuum, as he explains in detail. The diagnosticum can be made from any bacteria of the agglutinating type, and all seem to work well. He describes its application in twenty cases of typhus, from the fifth to the twenty-seventh day of the disease, with comparative tests with fresh cultures of *Proctus X*. In one case agglutination occurred at 1:10,000 with the desiccated and 1:10,000 with the fresh culture; in other cases the desiccated was two and four times as sensitive.

- Vaccination with "Cow Pox." J. M. Leão.—p. 48.
- *Association of Leishman Bodies and Fusospirillar Infection. A. da Matta.—p. 50.

Racial Color in Vital Statistics.—Leão emphasizes the necessity for specifying in vital statistics the color of the skin, so that whites, Indians, negroes and mulattoes can be classed separately and the pathology of each class better studied.

Intestinal Parasites.—Leão says that the perverted appetite which impels certain persons to eat dirt and other unsuitable substances is the effect of the anemia resulting from the blood-sucking action of certain helminths, plus the toxic action from their secretions and products. This perverted appetite or *picada* of these *papa-terras*, as they are called, is instructive evidence of the presence of trichocephalus or hookworm. In addition to the usual means recommended for treatment, he advises an infusion of the leaves of a plant, the *pipi* or *mucuracá*, (*Petiveria alléca*) which, he says, expels tenia, round worm, hookworm and the oxyuris, and reduces the number of the ova of the trichocephalus. The washed fresh leaves are crushed and a tablespoonful of the juice is taken fasting, followed by a glass of water and, two hours later, a purgative. Children are given 5 drops of the juice for each year, in a little water followed by a little more water, and two hours later half a tablespoonful of castor oil. The dose is repeated every second day, for four or more times. Santonin is not effective for any helminths except ascarides, he adds. The last meal of the day before should be merely tea or coffee with milk and *bolachas*.

Leishman Bodies Plus Fusospirillar Infection.—In da Matta's case, in the long chronic lesions on foot and leg of superficial leishmaniasis, insospirillar bacteria of the Vincent type were found in the ulcerating parts of the sores.

- *Influenza Psychoses. C. Alvarez and T. Fracassi.—p. 197.
- *Symmetrical Gangrene. F. E. Solari.—p. 211.
- *Transverse Prostatectomy under Local Anesthesia. M. A. Llanos.—p. 220.

Radium Therapy.—Jenquières reviews his extensive experience with radium therapy for almost all kinds of skin lesions and tumors, emphasizing in conclusion that radium should not be regarded as the last resort but should be considered among the earliest measures to be applied. He says that the indications for it are well defined, and that it is the preferable treatment for many medical affections. He adds that as radium respects the organ of vision, it has been used to advantage for epitheliomas of the lid, etc., without interfering with vision. But with ulcerating neoplasms and recurrences requiring new, long and numerous exposures, the eyeball becomes atrophied, with complete loss of vision. When an epithelioma of the mouth heals under radium, there is no disfigurement as after resection. Only vegetating cancers in the mouth, he adds, are amenable to radium. The ulcerating, infiltrating cancers are extremely rebellious, and he always advises their surgical removal to begin with; this does not have to be very mutilating, as the application of radium to the surgical wound satisfactorily completes the treatment. With epithelioma of the skin, the global destructive action of the radium for one or two hours in all may be preferable, but in all other forms the exposures should be prolonged for twelve, twenty-four or thirty-six hours, every two or four weeks, till the cure is complete. Sarcomas yield to radium the more readily the nearer they are to the embryonal type. It is important to strike hard, as sarcomas become generalized so readily. With chronic eczema and horny growth of hands and feet, he has obtained under radium most gratifying results, far surpassing those obtainable by any other measure. He has had cases of ferocious vulvar and scrotal pruritus subside under the third global irradiation (without filter) of a few minutes' duration, and the cure was complete for months. Any recurrence yields promptly to the same. The basal cell, pavement cell, and cylindric cell cancers are most amenable to radium therapy, the lymph glands not being involved early. The spindle cell and nevus cancers promptly extend to the lymph glands, and are sometimes refractory to radium. With any ulcerative cancer on mucous membrane, it is almost hopeless to apply radium therapy in the overwhelming majority of cases.

Influenzal Psychoses.—Five cases are described. The influenza had not been severe and the psychoses subsided in these cases in less than three or four months.

Symmetrical Gangrene.—In Solari's case the fingers dropped off of both hands and the gangrene of the legs extended from the toes up on the thighs. The patient was a farmer of 40 with no history or signs of syphilis or malaria, and he did not drink or smoke. Chilliness in the feet was the first symptom; then there were pains. These symptoms appeared at times during seven months, with intermissions of three or four weeks. Then the symptoms became more severe and the hands were involved. The eleventh month the extensive and progressive dry gangrene developed in hand and legs, with patches on the brow and ears. As a last resort treatment as for syphilis was pushed but no benefit was apparent, and the man died the thirteenth month.

*Arrested Development of Ectoderm. J. Strandberg, —p. 1.

*Recurring Puerperal Polyneuritis. M. Vallberg, —p. 13.

*Decrease in Eosinophils with Serum Sickness. E. Kälén, —p. 35.

*Clinical Significance of Tube Casts. R. v. Jakobsen, —p. 43.

*History of Syphilis in India. J. Charpentier, —p. 47.

*Death under Roentgen Treatment of Exophthalmic Goiter. K. Secher, —p. 63.

*Extrapyramidal Pseudosclerosis. G. Söderbergh, —p. 71.

*Cerebellar Tremor. G. Söderbergh, —p. 97.

Arrested Development of Ectoderm.—Strandberg describes in detail a case of various malformations from arrested development, including entire absence of teeth and atrophy of the skin which has scanty pigment and no sweat glands or hair. The man is a factory owner of 39, otherwise healthy except for a nasal affection resembling ozena. This was pronounced also in three of five analogous cases Strandberg has found on record. He notes the analogy also between the case here described and the normal development of the ectoderm in whales.

Recurring Puerperal Polyneuritis.—In the case reported by Vallberg the woman of 34 had had the toxic polyneuritis return at each of her three childbirths, without a trace of it in the interim. Paresis of accommodation was a special symptom, along with the paralysis of all the limbs. These symptoms developed five weeks, three weeks or eleven days after the delivery, and they subsided completely in ten or eight months. The woman was otherwise healthy, and there was absolutely nothing to suggest exogenous toxic action. He has been able to find only seven similar cases in the literature, and only one of them is beyond question; in two the polyneuritis developed during the pregnancy. In the others, only the arms were involved. Vallberg's own case was far the severest of all. He calls attention in particular to the similarity of the clinical picture in each attack; either the special nerves involved are constitutionally inferior or exceptionally susceptible to the neuritis-producing toxin.

The Clinical Significance of Tube Casts.—Von Jakobsen reiterates that the appearance of large numbers of cylindroids is a characteristic sign of disturbance in the circulation in the kidneys. With acute disturbance, as from occlusion of the renal artery by an embolus, the long and extremely narrow hyaline casts stretch across several fields of the microscope, and are beset with dense clusters of red corpuscles. Ribbon-like casts or cylindroids of this kind seem to be pathognomonic of an acute disturbance in the circulation.

History of Syphilis in India.—Charpentier is instructor in Sanskrit at the University of Upsala, and he calls attention to some hitherto overlooked data in Sanskrit literature which throw light on the history of syphilis.

Fatality Under Roentgen Treatment of Exophthalmic Goiter.—Secher reports the case of a previously healthy woman of 39, who had developed exophthalmic goiter in the course of a year. He gave eight roentgen exposures in two days, each a one-half Sabouraud-Noiré dose, with a 2 mm. filter, exposing three fields on the thyroid gland and one on the thymus. The condition became aggravated even during the roentgen treatment, and the condition grew rapidly worse till death the fifth day. He reviews the three cases on record in which roentgen exposures of simple goiter were followed by symptoms of exophthalmic goiter. In Kieler's and Vennig's cases the aggravation proved speedily fatal, as in the case here described.

Extrapyramidal Pseudosclerosis.—Söderbergh reports a case of Wilson's pseudosclerosis in a boy of 14½. The

movements in nearly all the muscles are strikingly slow and stiff, but the hyperionus differs from that with pyramidal lesions.

Norsk Magazin for Lægevidenskaben, Christiania

August, 1919, **so**, No. 8

*Orthostatic Tachycardia. S. K. Mordre.—p. 801.

*Brain Abscess of Nasal Origin. K. Haugseth.—p. 822.

*Ether or Thymus Death? T. Cappelen.—p. 826.

*The Antibodies with Allergy. A. de Besche.—p. 830.

*Inheritance of Tendency to Twins. K. Bonnevie.—p. 847.

Orthostatic Tachycardia.—Mordre discusses the pathogenesis of orthostatic tachycardia and the action on it and on dermographism of atropin and of epinephrin and of mechanical influences. The main factors in orthostatic tachycardia seem to be an instability of the vegetative nervous system, an orthostatic enteroposis, and an orthostatic drop in the blood pressure. The findings in thirty-five cases are compared. The pronounced degrees of orthostatic tachycardia were associated with sympathetomy in six of his eleven cases. A neurotic tendency was frequent in this group. One of the men in this group had urticaria and phenomena suggesting vagotomy, and yet he gave a pronounced response to epinephrin. Such cases testify to the close connection between the vagus and the sympathetic systems. Dermographism does not parallel the orthostatic tachycardia.

Brain Abscess of Nasal Origin.—Haugseth trephined through the temple region when the girl of 14 developed symptoms of a brain abscess following acute frontal sinusitis after influenza. As the rear wall of the sinus was found apparently intact, he refrained from puncturing here, and made the trephining opening through the sound tissue in the temple region. The opening discharged secretions for about five weeks but complete recovery ensued by the end of the sixth week, when the girl left the hospital. She was in perfect health when seen four months later.

Ether or Thymus Death?—Cappelen found that the thymus extended far down in the thorax in the man of 20 who died from respiratory paralysis after scopolamin-pantopon-ether general anesthesia for an operation for a tendon sheath phlegmon on the left middle finger. He never roused from the anesthetic, and stopped breathing, but the heart action kept good during four hours of artificial respiration. Then signs of pulmonary edema developed, and death occurred five hours after the close of the anesthesia. The passage of air was free throughout. The thymus measured 8 by 3 by 3 cm. and weighed 35 gm. and Cappelen regards this persisting thymus as the explanation of the fatality. The doses of the anesthetics had been injection of 1 mg. of the scopolamin and 2 cc. of the pantopon, and about 100 gm. of ether (Norwegian) had been used.

The Antibodies with Constitutional Hypersensitiveness, Asthma, Hay-Fever, etc.—De Besche has continued the researches and experiments of which a summary was given in these columns, June 8, 1918, p. 1804, with editorial comment, p. 1765. His present research deals with bronchial asthma and hay fever. In 14 cases the asthma was brought on by the smell or touch of the skin of a horse, in 3 by cats, and in one each by dogs and cows. He found that the blood of these persons contained specific precipitins for the albumin of the animal in question or the solution of albumin inducing the reaction. The responses were not always positive, varying at different times. They were negative in 2 cases directly after the attack of asthma had been elicited. This is interesting in connection with the disappearance of all symptoms in one case after a shocklike condition brought on by injection of horse serum. There were no further signs or symptoms of the asthma for three or four months thereafter, even when in close association with horses. This harmonizes with the findings in experimental anaphylaxis, especially as the condition can be passively transferred to others. The present other data, including Walker's findings, which seem to sustain his assumption that there is a production of specific antibodies in these hypersensitive persons, and that these antibodies are mainly cellular, but occasionally they can be found in the blood in large amounts. The

anaphylactic reaction-body may circulate in the blood, and the anaphylactic tendency can be passively transferred to guinea-pigs by injection of this blood serum. Instances are known of hereditary transmission of horse asthma. Some anomaly in the resorption or in the metabolism of albumin seems to be the cause of the disturbances. A large quantity of antibody and a small amount of antigen may cause the death of the animal with experimental anaphylaxis, as likewise a small quantity of antibody and a large quantity of the antigen.

Twins in Certain Families.—Bonnevie here presents the second official communication from the Christiania University Institute for Research in Heredity. A genealogical chart is given through nine generations of a family, covering 150 years and 5,000 members, with 1,300 married couples. One branch of the family had twin or triplet births in 7.7 per cent. of the total 1,151 childbirths, while no twins were known in the 2,260 births in the other branch of the family. Eight of the twin-birth mothers bore twins or triplets more than once, and the families with twins were somewhat larger than the average. The mothers of the twins with one ovum were generally younger women, but 80 per cent. of the twins were of the two-ovum type. In the entire chart there is not an instance of twin birth in which the inherited tendency to twin births can be excluded on either side. The tendency to two-ovum twins behaves like a recessive character. The twins themselves did not seem to breed twins more than the other members of the family.

Influenza at Thorshavn. K. Biering.—p. 1176.

Public Health in Germany at Close of War. A. H. Hoff.—p. 1181.

Roentgen Treatment of Exophthalmic Goiter.—Nordentoft has another series of fifty to add to his fifty cases of exophthalmic goiter given roentgen treatment. His conclusions are practically the same as from his first series (reviewed in these columns, Nov. 16, 1918, p. 1702). The later and the continued results in his first series have been equally favorable. The details of some specially striking cases are given, including one in a man of 33 two of whose cousins and a sister also had exophthalmic goiter. His symptoms suggested that the thymus and vagus were mainly involved (subjective heart symptoms with moderate pulse, sweats, thirst and dizziness with extreme exophthalmos). The symptoms subsided under exposures of the thymus and part of the thyroid and later of the thymus alone. There were only eight men in his total 100 cases, and they were mostly of this thymus type. He regards small roentgen doses as only irritating, while a single large dose has a destructive action from the first. If there is any risk with roentgen treatment of exophthalmic goiter it is with repeated small doses. Prudence requires a full dose applied at one sitting. Referring to operative treatment of exophthalmic goiter, he mentions the fatal outcome in fourteen of the seventy-six operative cases at the Rigshospital. In conclusion he urges the advantages of change of scene and other measures to combat the instability of the nervous system common with exophthalmic goiter.

SOME OF THE THINGS THAT ORTHOPEDIC SURGERY HAS DONE FOR THE WAR

AND THAT THE WAR HAS DONE FOR ORTHOPEDIC SURGERY *

EMIL S. GEIST, M.D.

Assistant Professor of Orthopedic Surgery, University of Minnesota Medical School

MINNEAPOLIS

Today few of us would agree with Hippocrates, who said that "war is the only proper school for the surgeon." Nevertheless, wars, as a rule, have furthered the progress of the healing art. All branches of medical science have been benefited. The original work of Larrey during the Napoleonic wars was great. He was the first to amputate successfully at the hip. He established first aid and was the first to use ambulances. Esmarch described, during the Franco-Prussian War, the subject of wound excision, practically the débridement of today. The Boer War showed us the benefits of mass antityphoid inoculation; while the advances made in the prevention and care of yellow fever by Reed, Carroll and Gorgas are the result of the Spanish-American War.

It is premature for any one to predict what changes in medicine due to the recent great war will in the future be recognized as progress. Nevertheless, we can say with little fear of contradiction (*a*) that the Carrel-Dakin principle of wound sterilization has come to stay, and (*b*) that orthopedic surgery, as a specialty, has fully justified its *raison d'être* and is here to stay.

Orthopedic surgery has scored a great victory. This section is not only joining in the world-wide paean of jubilation over the definite and final success of Democracy over Autocracy, of Right over Might, but also it is justly celebrating the triumphs of orthopedic principles and practice over the deformity and crippling which threatened to blast the lives of our fellow citizens.

That this is so is due to the small but stalwart band of allied orthopedic surgeons who existed in 1914 and who were under the spiritual leadership of that Foch of orthopedic surgery, Sir Robert Jones, of England; we Americans were ably led by our own beloved Brackett of Boston.

Difficulties had to be encountered; difficulties not only due to the paucity in number of this body and its ignorance of military ways and means, but also due to

a general lack of appreciation of the importance of principles long known to orthopedic surgeons. One cannot be an orthopedic surgeon without being able to think "orthopedically." The expression "orthopedic thinking" is no misnomer. Thus, it came that, at the outset, there were too few who had been trained to treat and prevent potential deformities; there were too many who treated the injury well, but who had not been trained to think of future function.

The difficulties were unavoidable, and in the vast number of cases due to honest misunderstanding. They had all been overcome on the historic 11th of November—on which date American orthopedic surgery, like the American army, was just "getting its gait."

When orthopedic surgery dons her military garb and contemplates her features in the mirror of events, she will find that changes have occurred. She is now grown up; her field of endeavor is enlarged. In the decade preceding the great war, she had already reached advanced, awkward adolescence; and even then, she ministered increasingly to the adult cripple and his problems. From now on, she will find herself facing the cripple problem in its entirety and she will have to join with municipality, state and Union in order to solve it properly. Leadership lies before her in the care not only of the child cripple, but also of the industrial cripple; not only of the actual cripple, but also of the potential cripple.

In 1914, the orthopedic surgeons of England were noted more for quality than quantity, and it was necessary for us to send over a large group of Americans for purposes of temporary relief. This and other factors due to the war have brought about a unique, cordial relationship which promises to be of mutual advantage in the future.

A flood of orthopedic literature in the form of textbooks, monographs and articles has appeared. Some of it will have only historical value, whereas the experiences recorded in a considerable part of it will always remain as living guidance for peace time work. The task still remains for some one to separate the kernel from the chaff.

Standardization was attempted and achieved in many orthopedic fields. In this country, the standardization of splints is perhaps the most noteworthy example, while in England operative methods and postoperative care were perhaps most successfully standardized.

Many new types of splint and many new methods of cure have been found efficient. Most of them are the products of the fight against that *bête noire*, infection. Fortunately, we have less occasion to meet this enemy in civilian life, and fortunately the terms débridement,

* Chairman's address, read before the Section on Orthopedic Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

primary suture, secondary suture, guillotine, will occupy a minor, though necessary, place in our applicable stock of expressions.

If the war had lasted longer, we might have had solved and standardized for us the vexatious foot problem. The very multiplicity of solutions for this problem argues here, as elsewhere in medicine, that the real answer has not yet been found. It would appear that the anterior heel described a long time ago by Ansel G. Cook has found all but universal favor in certain disorders, and its originator ought to get the credit for it.

Fractures were to a great extent put under the care of the orthopedic surgeon in American overseas hospitals. For this reason, there existed a remarkably small percentage of preventable deformity in the cases which reached this side of the Atlantic. There is no doubt that in future civilian practice, the orthopedic surgeon will be called on to treat in a greater degree than ever the fractured bone.

The psychology of the wounded soldier still under military control is different from that of the ordinary civilian patient, and perhaps also varies from that of the injured industrial employee. If so, the experiment of the curative workshop as applied to civilians will be followed with interest. If a success here, it will certainly put the Zander room on the scrap heap.

It would appear that electricity, in the form of the Bristow coil, is again seeking admittance to the ranks of our armamentarium. If we readmit electricity, let us make sure that it plays no pernicious pranks such as it did before we discarded it, as we thought at the time, forever.

A number of schools in military orthopedic surgery, more or less efficient, ground out, in the course of a few months, a considerable quantity of young "war" orthopedic surgeons. Many of these were stationed in positions in which clinical advantages were great. Of these conferees, many will, no doubt, wish to remain in the orthopedic field. To these, I would say, "Welcome." But I would add to this welcome, a little whispered advice. This advice would be: "You have seen much of war orthopedic surgery; it is doubtful if you have seen it all; but even if you had, you would not by virtue of that fact be fitted for civilian orthopedic surgery. It is quite different. Go to Boston! Go to New York! There is no better place for you in this wide world. And stay there long; long enough to master what you will see and hear and think about while there."

It was almost providential, as a result of peace time efforts, that we were well prepared to take charge of two important types of cases. I refer to the bone graft and the tendon operation. The principles of the former were well understood and were applied whenever needed. In numberless cases of peripheral nerve injury have tendon transplantation and tendon fixation operations yielded definite, well anticipated results. It may be safely said that for every case demonstrably improved by operations on nerve tissue, there have been ten bettered by some form of tendon operation. At this point, we must not forget to mention the knowledge which we were able to apply in paralytic cases in the prevention of deformity and the prevention of muscle stretching, which knowledge was gained from the study of the thousands of cases of infantile paralysis in the decade preceding the war. Little did

any of us think that these afflicted children were helping to solve the paralysis problem of their big brothers.

While many changes have taken place and many new devices and methods have been originated by the war, nevertheless, the orthopedic surgery of the war was founded on the true and trusted principles discovered and laid down during peace time by thinking orthopedic surgeons in their laboratories and their clinics.

And now, one by one, we again turn to these havens of peaceful endeavor, leaving behind us the confusion, glamour, trappings and horror of war.

Nearly to a man did we orthopedic surgeons join in this war. We are glad we were in it; glad that we carried on. We are also glad to leave it. We feel that we have given much; but we have also learned much.

CONSERVATION OF VISION, AND BETTER OPHTHALMIC PRACTICE *

CASSIUS D. WESCOTT, M.D.

CHICAGO

[The chairman, after discussing various measures relating to the Section on Ophthalmology, proceeded:]

Much has been done by our special committee, and by individual members of the section, to spread the gospel of conservation of vision; but we must do more. The problem of the protection of the baby's eyes is fairly well in hand, though much remains to be done in some states. But the experience of the selective draft has called attention to defective vision in young adults, which was to say the least surprising. My own experience on an advisory board impressed me with the enormous number of cases of rejection for myopia, uncorrected, or very imperfectly corrected. In talking with the men about their eyes, I found that the neglect was due to their own ignorance and that of their parents, or to the fact that they had been imposed on by opticians who had sold them glasses without advising them to seek medical advice. In the present state of our knowledge, it should be unlawful for any one not a trained ophthalmologist to undertake the correction of myopia in a child or a young adult. I doubt very much if any legislation which we might initiate would reach the optician or the optometrist, but I wish they might at least be apprised of the harm they are doing by depriving people of proper care.

In my talks with prescribing opticians, I have held that they should never prescribe lenses which did not give the patient normal vision with each eye, and that they should not attempt to fit children. But the observance of these rules would not enable them to avoid sinning, for as we all know, there are many cases of incipient cataract, glaucoma and other serious conditions in which normal vision is possible, to say nothing of myopia and myopic astigmatism. Obviously the remedy is to educate the people.

The question is how best to do it, and what can we, as an association, do that we are not already doing? I think we should provide for more pamphlets and more public lectures, and do more as individuals and keep everlastingly at it. At the risk of seeming egotistic, I am going to tell you what I have tried to do

* Chairman's address, read before the Section on Ophthalmology, at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

myself. I practiced general medicine for ten years, and have never been able to get away from the human side, even in a practice limited to ophthalmology. The correction of an error of refraction involves a consideration of the patient's general health as revealed by the anamnesis, or suggested by the external examination and the use of the ophthalmoscope. I find myself discussing with younger patients the choice of an occupation with reference to the condition of the eyes, and the general health; with older people the importance of regular and frequent general examinations in order to keep well, and retain full efficiency. I advise all patients to have the eyes looked over once a year at least, and a complete examination, with the use of a mydriatic, every two years, or oftener, as indicated. In answering the questions of intelligent patients and informing the ignorant, I have found the pamphlets of our conservation series a great help, and hand them out daily in my office. I have taken particular pains to supply the teachers and mothers of families with these admirable helps. I find that some of the pamphlets have passed through many hands, and I am frequently asked for more. I have given a number of public lectures, and in my talks to nurses and medical students for over twenty-five years have tried to make a missionary of conservation of each one of my hearers. I have grown more or less hopeless in regard to the matter of annual school examinations by the teachers, introduced and so strongly advocated and made so simple by Dr. Allport. It has never been done effectively in Chicago, and I often see children who have been in our public schools for years without a visual examination until increasing myopia made a front seat a necessity. The visual examinations which are made now are made by school nurses and school physicians only on complaint of the teacher. When all our politicians have completely lined their pockets with gold, we hope to have several things done which are now neglected.

The American Board for Ophthalmic Examinations was organized because of the obvious need of some systematized and standardized training for those who are to practice ophthalmology. You are all familiar with the good work it has done and is doing. As individuals we should encourage as many as possible to take the examinations of this board. The qualified should be recognized and honored by the certificate of the board; those who are unfit should be made aware of their shortcomings, and encouraged to qualify themselves by further study and training. In this connection I would like to quote from a paper by Dr. Edward Jackson:¹

An organization like this could arrange to give, just before its annual meeting, a week of intensive training on the microscopic diagnosis of intra-ocular tumors, under three or four of its members who have given special attention to ocular pathology. Or, to make the best use of the time with the least strain of any one set of powers, this might be combined with a similar course on experimental optics, or the minute anatomy of the eye with reference to operations on the anterior segment, or the location of foreign bodies. Such courses should be put on a basis of fees that would compensate the instructors, and provide the necessary material or equipment. Similar courses could be arranged by local ophthalmologic societies for the benefit of their own members, and to suit their convenience.

Finally, it would help to remove the greatest defects in training for ophthalmic practice, it would emphasize the

importance of fundamental training, if the American Board of Ophthalmic Examinations would divide its examinations into two parts. It could give to students who have been out of the medical school one year or more an examination on ocular anatomy, the physiology of vision, geometric, experimental and physiologic optics, and ocular pathology. Two or more years later it could give the examination in ophthalmoscopy and other branches of clinical diagnosis, clinical examination of patients, therapeutics and operative technique. Something of this kind is needed to prevent the essential preliminary work from being neglected, and to prevent such neglect from impairing the value of all training in the so-called practical branches.

These are admirable suggestions, and I wish they might be seriously considered by the section. We should certainly do all we can individually and collectively to discourage and discontinue short cuts to ophthalmic practice. I am often asked to teach men refraction or recommend schools where it can be learned in a few weeks. I invariably tell these men that it cannot be done and beg them to devote at least a year to preparation, explaining that the ability to do a good refraction is only one of the obligations assumed by the physician who would essay it. Some of my most grateful patients are among those who have learned during an examination for glasses that they were not so well as they thought they were, and that the ophthalmoscope is a great aid in general diagnosis.

I think we should also do something toward the standardization of undergraduate ophthalmic teaching. Iritis is still being treated with boric acid and argyrol; acute glaucoma with atropin, and sufferers from chronic glaucoma are being told that they must wait until they are quite blind before the cataract can be removed. The more I know about ophthalmology the more interesting the eye becomes in relation to general diagnosis, and the more convinced am I that physicians generally are not taking advantage of their opportunities. I am also sure that it is not their fault—entirely. They haven't been taught. Several men who served on local boards in and near Chicago during the draft were not able to follow the simple directions given them for taking the vision. But the need has been so well and so recently brought out by Dr. Woods, Dr. Jackson and General Munson and by the Council of British Ophthalmologists that I am sure I need say no more. I feel quite confident that the Council on Medical Education will be glad to consider suggestions from this section on undergraduate medical teaching in ophthalmology, and I hope I may be asked to appoint a special committee to study and report on this subject.

I think it would also be well for us to consider and give our endorsement to a compensation table. The present methods of estimating compensation for ocular injury are very unsatisfactory and incomplete, and to some seem unnecessarily complicated. I would be glad to appoint a committee to study this question with a view to preparing something which may be presented as authoritative to the legislative bodies and compensation boards.

In conclusion, I cannot resist the temptation to express what I know you all feel, our very great pride in the work of members of this section in the service of our country. We are glad to see many of them back from service, and with us today, and thank heaven that they could go.

22 East Washington Street.

1. Jackson, Edward: Defects in Education for Ophthalmic Practice, *Tr. Am. Acad. Ophthalm. & Otolaryng.*, 1917, p. 144.

series a two stage operation was performed, and in the second series a one stage operation. In the first series one animal lived twelve days, and in the second, one animal lived three months. None of the duodenectomized animals, however, appeared to keep in good condition.

Grey¹⁴ removed the duodenum in three stages, leaving an interval of several weeks between each stage. One of his dogs survived all three operations (complete removal of the duodenum), and remained in perfect health for eight and one-half months.

Moorhead and Landes¹⁵ also used a three stage operation for the removal of the duodenum. They were able to remove the entire duodenum and to demonstrate that dogs are able to live in perfect health after such a procedure.

Dragstedt and his collaborators clearly showed that a dog can survive duodenectomy, but their work is open to the same objections as that of many of the earlier workers, namely: The duodenectomy was complicated by a loss of pancreatic, and, in some instances, of biliary function. As they suggest, this probably was the cause of the failure of their animals to maintain health. The results of Grey, one of whose animals lived the longest after duodenectomy, and of Moorhead and Landes, prove that duodenectomy is compatible with life and perfect health in the dog for relatively short periods.

TECHNIC

In the first experiments we attempted a two stage operation for the removal of the duodenum. However, as it was our intention to make extensive studies of the gastro-intestinal tract and the various organs after duodenectomy, it was soon seen that by the time the second stage of the operation was performed the many adhesions would greatly complicate our studies. We attempted to devise a one stage operation by combining the two stage operation in one. We had a few successes by this method. One animal survived forty-one days, but in this case the pancreatic ducts were ligated.

On account of these unfavorable results a new method was developed, and two points were accomplished: (1) The duodenectomy could be performed quickly, and (2) all the other involved organs, such as the bile duct, both pancreatic ducts, the pancreas and the alimentary tract, were restored to correspond as nearly as possible to the normal state. Briefly described, the operation consists of four steps:

1. The dissection of the duodenojejunal fold, the mesoduodenum and the lesser omentum; and the ligation of the blood vessels supplying the upper jejunum and duodenum.

2. The separation of the pancreas from the duodenum and the isolation of the major pancreatic duct and the common bile duct, together with the minor pancreatic duct.

3. The removal of the entire duodenum, with a portion of the proximal jejunum and the distal pyloric portion of the stomach.

4. The implantation of the bile duct and the minor and major pancreatic ducts into the jejunum.

The technic described was developed on the dog, and, with slight modifications, it was found to be adaptable to several other species. The operation could usually

be performed on the dog within from one and one-quarter to one and one-half hours, never longer than two hours. Several of the animals died as a result of the operative procedures before we had developed our technic. Others died from the results of intercurrent disease. After our technic was fully developed, however, practically all the animals lived.

RESULTS

Our results on dogs fully corroborate those of the more recent investigators. The animals quickly recovered from the operation and, with a few exceptions, have remained in excellent health. Their general condition has been good; their weight usually has increased or remained stationary. A few of the animals steadily lost weight and strength after the operation. At necropsy, or at exploratory operation on these animals, a dilated common bile duct and marked infection of the entire biliary tract were usually found. Evidently the transplantation of the ducts did not restore a condition sufficiently normal to prevent infection.

Examination of the blood to determine the cell count, hemoglobin, carbon dioxide combining power and hydrogen ion concentration did not reveal anything abnormal.

Examination of the gastro-intestinal tract by the roentgen ray, employing a standard barium meal, showed only slight deviation from the normal. In some instances, the barium left the stomach sooner than in the normal dog, probably because of the loss of the pyloric sphincter. At other times, it seemed that the emptying of the stomach was slightly delayed and that the course of the meal was a little slower, but in each instance this delay was not any greater than in some of the normal animals. In general, however, no difference was noted in the passage of the barium meal in the duodenectomized and in the normal dogs. Roentgenograms of the gastro-intestinal tract appeared normal. Future studies may show some effect of duodenectomy on the mechanics of digestion, but at present none have been noted.

REMOVAL IN OTHER ANIMALS

Up to this time all experimental duodenectomies, with the exception of a few on the frog, had been done on the dog. At the suggestion of C. H. Mayo, we attempted to determine the effect of the operation on other species, particularly on the herbivorous and omnivorous animals.

The duodenum was removed from the cat. The operation is easily performed on this species. It is necessary to transplant only one pancreatic duct, that which enters in conjunction with the common bile duct, as the other duct is quite small.

The goat was selected as a suitable type of herbivorous animal. The operation is difficult in this species. The duodenum is long; the length of intestine removed measured about 90 cm. As the pancreatic duct empties directly into the common bile duct, it is necessary to transplant only the latter. The thin walls of the jejunum make the anastomosis quite difficult.

The hog was selected as an omnivorous type of animal. The removal of the duodenum is very difficult in this species. As the bile and pancreatic ducts empty separately, two transplantations must be made. For expediency and in order to remove all the duodenum, as in operating on the dog, it was found best to section at the duodenojejunal juncture, invert the end of the

14. Grey, E. G.: Demonstration of a Duodenectomized Dog. *Bull. Johns Hopkins Hosp.* **29**: 152 (June) 1918; Duodenectomy: Its Effect On the Life of an Animal; Transplantation of the Pancreatic Duct. *Surg., Gynecol. and Obst.* **28**: 36-42 (Jan.) 1919.

15. Moorhead, J. J., and Landes, H. E.: Duodenectomy. *J. A. M. A.* **72**: 1127-1129 (April 19) 1919.

jejunum, and unite the jejunum slightly more distally to the end of the stomach.

The duodenum was also removed from the monkey (*Rhesus*), its anatomy being similar to that of man. It is necessary to transplant only one duct in this species, since the minor pancreatic duct can be ignored.

We now have ten dogs, one goat and one hog from which the duodenum has been removed. One of the ten dogs was operated on six months ago. All the animals, with the exception of one dog, are in good condition.

SUMMARY

The investigation was undertaken for the purpose of determining the effects of the removal of the duodenum. A one stage operation for the removal of the duodenum was developed. The duodenum was removed from the dog, cat, hog, goat and monkey. Careful studies on the dog did not reveal any noticeable changes following the duodenectomy. The animals remained in good condition. Examination of the blood showed it to be normal with regard to cell counts, hemoglobin, carbon dioxide combining power and hydrogen ion concentration. The roentgen ray showed the course of a standard barium meal to be practically the same as in a normal dog. Experiments on the other species have been too recent to allow conclusions to be drawn, but it would seem that the removal of the duodenum in the hog is as innocuous as its removal in the dog. No data have been secured to show that the duodenum is of great importance in any of the species used. Future studies with particular reference to gastric secretion, etc., may give more positive results.

ABSTRACT OF DISCUSSION

DR. W. M. L. COLEIN, Philadelphia: Has the sugar metabolism been affected?

DR. FRANCIS CARTER WOOD, New York: What was the time required for such an operation?

DR. FRANK C. MANN, Rochester, Minn.: I have studied the evidence with regard to glycosuria in a very elementary way. In the animals I examined the sugar metabolism seemed to be normal. We made no tests, but the increase in weight and the good general condition seemed to indicate that there was no change. The operation is easily performed on the cat; it can be done in an hour, but cats have not nine lives from a surgical standpoint. They are the very poorest animals on which to do experiments. The operation can be done in one hour and a half on the dog. It takes longer when done on the goat and hog.

Cost of Blindness \$31,000,000 Yearly.—It is estimated that the total annual expense of the blind to the country approximates \$31,000,000. There are 70,000 blind persons in the United States. Of this number 41,000 are absolutely dependent on others for support. Apart from the economic loss caused by the removal of productive workers from the wage-earning class, there is added a financial burden in direct interest of the blind. A large item is the maintenance of special schools for blind children. It takes far more to educate the blind than the normal child. Including the expense of institutions, library facilities, home teaching, the amount soon approaches millions. Considering every phase of the question of costs, it is estimated that the total annual expense of the blind to the country approximates \$31,000,000. Fifteen million dollars can be saved annually by the united efforts of education to avoid the many accidental cases of blindness in the industries by the prevention of lost vision caused by bad eyes, sore eyes, measles, ulcers of the eyes, scarlet fever, trachoma, occupational diseases, wood alcohol poisoning, excessive use of alcohol and tobacco and uncorrected visual defects.

CLINICAL TYPES OF OCCUPATIONAL DISEASES

STUDY OF METHODS FOR THEIR PREVENTION*

LOUIS I. HARRIS, DR.P.H., M.D.

Director, Bureau of Preventable Diseases, Department of Health
NEW YORK

More and more, physicians are beginning to appreciate a marked change in the spirit of the times. It has long been recognized that this is an era of great industrial development, but up to the present time only a relatively small number of physicians have discerned the far-reaching influence which industrial development is beginning to exercise on general medicine, surgery and preventive medicine. It requires no special gift of prophecy to foretell the time in the near future when many physicians, who, during the last few years, were wont to look on industrial hygiene and the study of occupational diseases with good-natured indulgence, or with more than a little of a certain air of condescension, will very seriously have to consider the readjustment of their practice to fit in with the needs of industrial medicine. Whether as a result of health insurance, or through a desire on the part of employers to comply with the insistent demand of the working people for effective protection of their health, it may be stated with assurance that industrial hygiene, industrial surgery and industrial medicine are bound to emerge clearly into view as most important special branches of modern medicine.

In its efforts to prevent occupational disease, the Division of Industrial Hygiene of the New York City department of health, as organized up to Jan. 1, 1919, received complaints from individuals and from labor organizations, and requests for advice and counsel from employers. These complaints and the requests for assistance time and again led to many investigations which brought us face to face with conditions of great interest, and showed that there exist in factories thousands of cases of illness which are either ignored or unsuspected. The sources of danger to the lives and health of workers from various chemical poisons and dusts, and from exposure to other hazards, can only briefly be illustrated here by the citation of several interesting experiences.

CARBON MONOXID POISONING

It came as a great surprise to those of us who are interested in this work to find nearly every winter, when windows and doors were closed—these being practically the only means of ventilation in many establishments—that a relatively large number of employees would simultaneously become ill from time to time, presenting a clinical condition which became fairly familiar with repetition. A typical instance was one relating to a factory situated on the three topmost floors of a twelve story factory building, given over to the manufacture of men's clothing. Of 125 employees, seventy-three became suddenly ill at about 2 o'clock one afternoon, and were seized with nausea and vomiting. Practically all of them complained of headache, dizziness and general weakness, which was particularly marked in the legs. A number were overcome, and

*Read before the Section on Pathology and Physiology at the Sixty-sixth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

several ambulances were called from nearby hospitals. Three employees were removed to hospitals, and a number of others were sent home under escort. Practically all recovered within a few hours, but in two cases symptoms of marked general weakness persisted for several days.

At this time, stories were current about the work of spies in impregnating the cloth used for manufacturing soldiers' uniforms with various poisonous substances. As the result, however, of several similar experiences in previous winter seasons, we felt reasonably certain that the condition was due to the improper removal of various gases of combustion, particularly carbon monoxid, and to their escape into the workroom. On investigation, in this particular instance, we found that our theory was apparently correct. But that the gas entered the working establishment from an unusual source. The rear doors of the three upper floors which communicated with a hallway that led to the roof had been left open by an employee, and a shift in the direction of the wind caused the chimney gases to be driven in considerable concentration down through a stairwell into the corridors, and then into the workrooms. When later we analyzed the facts in the case, we found that the employees who were affected were those who were at work near the rear of the shops where the doors were open.

What is more important from the standpoint of industrial medicine is this: We have found on a number of occasions during the past winter seasons that in connection with gas flames used for pressing-irons, or where furnaces were in operation, or, in fact, wherever incomplete combustion of gas or coke occurred, a clinical condition of a similar character frequently developed among large groups of employees. Altogether, about 220 cases of acute carbon monoxid poisoning, similar to the seventy-three cases referred to above, which were traced to the incomplete combustion of a variety of gases or fuel substances containing carbonaceous material, and in which acute symptoms followed exposure to these gases, came to our notice. Although, in several instances, careful examinations of the blood were made, we were not able to demonstrate the presence of carbon monoxid, but in the light of Prof. Vandell Henderson's investigations, showing that carbon monoxid in combination with the hemoglobin is readily given up in the presence of pure air, this can be readily understood.

Our examination of a number of men who were exposed to furnace gases and, particularly, a number of investigations which were conducted with reference to complaints made by persons employed in garages, have led us to believe that in industrial communities there are many persons who are affected with headache, marked anemia, general weakness and gastric symptoms whose condition is due in large measure to continued exposure to small amounts of carbon monoxid gas resulting from incomplete combustion. Numerous cases were called to our attention in which the private physician, having failed to ascertain the nature of the industrial environment in which a patient was employed, was apparently very much at sea to explain the cause of these symptoms.

The therapeutic agent of greatest value in the elimination of this source of complaint, which, we have reason to feel, affects many thousand persons in an industrial community like New York, is the application of simple sanitary engineering principles. It is neces-

sary to remove noxious gases by the installation of exhaust or suction fans and by devices which can be made an integral part of furnaces, of gas irons or of engines which generate fumes.

The rapidly increasing use of electricity as a source of heat in connection with furnaces and various mechanical processes will also, in large measure, reduce the danger of poisoning from this source. In passing, it should be stated that the industrial physician must work in close association with the sanitary engineer, and particularly with those who have made a specialty of installing systems of artificial ventilation.

APPARENT CARBON DIOXID POISONING

Three cases of poisoning of an unusual character came to our notice through the office of the coroner about a year ago. A freighter, which had carried a cargo of molasses, was moored in an inlet in New York, and had unloaded its cargo. The men used the inlet water to flush out the hold of the vessel to remove the molasses that had adhered to the walls and the bottom. This inlet water was very heavily polluted, and after the flushing had been carried on for a considerable period of time, one of the crew began to descend into the hold, but was overcome while still on the ladder, and fell to the bottom. A companion immediately attempted to go to his assistance. He too was instantly overcome and likewise fell. A third man, who made a similar attempt, was also affected and fell violently to the bottom, sustaining injuries to the skull which confused the subsequent clinical condition. Several men, who were lowered with ropes, brought the three who had fallen out of the hold. Two recovered promptly, but the third man, who had sustained a severe injury to the skull, rapidly became comatose and died in a short time. At necropsy, a depressed skull fracture was found; it was questionable to what degree the fracture was the factor operative in bringing about the fatal termination. The blood was found to be of an extremely dark color, fluid, and had a very distinct sweetish odor. The lungs were engorged. While it was difficult to say in this case that the man had died of carbon dioxide poisoning, it appeared from the nature of the cargo, and from the manner in which the gases that were generated in the hold following the flushing with inlet water had acted on the three men, that we were dealing in this instance with carbon dioxide gas which had been generated as a product of fermentation, and which had caused an acute intoxication that was responsible for the fall of the deceased. These three instances are of special interest merely because they are examples of the variety of forms of poisoning which may be encountered in industry, and which rarely come to the notice of public health authorities except in the event of a fatal termination. This is due to the fact that there is unfortunately not sufficient team-play between the clinicians in private or hospital practice and the public health officers interested in industrial hygiene.

ANTHRAX

We have had an average of eleven cases of anthrax reported in New York City since 1915. While the source of infection in a small number of cases cannot be explained, the majority of them occurred in persons employed in the handling of hides, and more particularly among brush makers. From investigations which we have conducted in 102 brush making establishments, we found that because of practical difficulties alleged

to exist, the sterilization of imported bristles, particularly those intended for use in making shaving brushes, was and is virtually, entirely neglected. The wonder is that we have not had more cases of anthrax.

One gains the impression from the study of conditions in Wilmington, Del., where an enormous quantity of hides is handled, and from other places where anthrax is likely to occur, that many employees have infections of varying degrees of severity which are diagnosed as erysipelas or ordinary infections, and which are principally characterized by extensive cellulitis. So many of these cases are found among workers in the brush-making industry and among those employed in the handling of hides, and occasionally among longshoremen, that one cannot but come to suspect that a relatively mild anthrax infection may be of far more frequent occurrence than we have hitherto believed, and that although we have regarded this as a disease which is almost invariably fatal, there may be mild as well as severe anthrax infections which are not properly identified and which are the result of industrial exposure. At all events, this is a subject the study of which would be extremely profitable. Practically all of the patients with anthrax seen in the city of New York during the last four years, in which the progress of the clinical condition was not rapidly fatal, have been treated by excision of the malignant pustule, and in a number of instances the Eichhorn serum has been administered, apparently with good results. Of the forty-four cases reported in the last four years in the city of New York, twenty-five terminated fatally.

CHEMICAL POISONING

Even to one who has an intimate knowledge of the industrial life of a community, it is a frequent if not constant source of surprise to learn of the multitude of unusual trades and industries which are conducted in many small establishments scattered through a big city. One little suspects that a number of chemical poisons which seem to interest only remotely the student of industrial medicine may be a potent agent for harm in a given community. A chemical agent which may seem to affect only two or three persons working in a small establishment must never be judged unimportant until one considers the total number of such establishments which may be handling the same chemical substances in various parts of the country.

For example, our experience and that of others have indicated that arsenical poisoning from the manufacture, trade use, or handling of various arsenic salts must be more frequent in New York City than many would suspect. The possibilities for poisoning from the fumes of arsenic-retorted hydrogen exist in steel and iron mills, as well as in a number of other industries in New York City, as elsewhere.

Hydrofluoric acid is a source of danger among those who are engaged in etching designs on glassware; it produces varying degrees of irritation and ulceration of the mucous membranes and of the skin. It, too, may be frequently encountered in a large industrial community.

With the great impetus which the war has given to the manufacture of dyestuffs in this country, anilin poisoning and other related forms of chemical poisoning are to be looked for as a frequent cause of disease.

The use of mercury in the manufacture of thermometers and other scientific instruments, and in the

manufacture of felt hats, is a far more frequent cause of mercurial "shakes" or tremors, cutaneous and mucous membrane ulcers, gastro-intestinal and nervous system disturbances, and early degeneration of the arteriovenous system than has been suspected.

The pathologic effects of lead in a multitude of trades have been harped on so often and so much as to have lost interest for the general practitioner; yet everywhere, in industrial centers, it continues to exist as a serious menace to the health of many. Judging from the number of reports of chemical poisoning in industry which private physicians and hospitals submit to health authorities and to medical journals as well, one would derive the impression that the types of industrial disease here briefly referred to, as well as many others which the limit of time does not permit one to enumerate, are almost nonexistent.

I may only mention, in passing, the patients suffering from poisoning resulting from trinitrotoluene and other explosives, among a number who returned disabled to New York during the war period, to indicate further the great range and variety of occupational diseases that one may encounter in a large city.

OTHER FORMS OF INDUSTRIAL DISEASE

Caisson disease occurs in scores if not hundreds of cases each year, in connection with the construction of tunnels and the excavation and construction of foundations for so-called skyscrapers in New York as elsewhere.

A fertile field for study of the peculiar and almost specific effects of stone dust was suggested by the reports made by the New York branch of the Granite Cutters International Association of America, showing that in one year, of 210 deaths occurring among members of this local branch, 50 per cent. were due to tuberculosis. How many other men, who died of pneumonia, were made particularly susceptible to the disease by the inhalation of sharp mineral dust could not be determined.

LEAD POISONING AMONG PRINTERS

One hundred and twenty-five printers were studied with a particular view to discovering the presence of symptoms indicating lead poisoning. An interesting feature of this investigation was the fact that by special arrangement with the president of a local printers' union, the examinations were conducted at union headquarters. Because our clinical data are not complete in all cases, only 100 cases have been included in this preliminary report. A few of the more striking facts elicited in the course of this examination will be presented. A more extended account, comparing the frequency of lead poisoning as found in 402 painters, with its frequency in these 100 printers, will be presented in the future. Twenty-six of the 100 compositors gave a history of cough of long duration; nine gave a history of recent bloody expectoration; thirteen were suffering from night sweats; nineteen had lost a considerable amount of weight or strength, and also had pains in the chest of varying degrees of severity; twelve gave a history of pneumonia; fifteen, a history of pleurisy; eight were subject to attacks of bronchial asthma, and twelve had chronic bronchitis. A family history of tuberculosis was obtained in nineteen cases in which the diagnosis of tuberculosis was made. Seventeen per cent. of these printers gave signs of arrested

or active pulmonary tuberculosis. Further study is needed in order to arrive at a final conclusion with reference to the total incidence of pulmonary tuberculosis in this group. Respiratory diseases were common among these men; the total number of such diseases being thirty-nine, or 35 per cent.

Muscular pains, which are characteristic in those who are exposed to lead, were fairly conspicuous. Thirty of those examined had a decided backache. Considering that these men were all compositors employed at linotype machines and seated in a constrained position during the work, this apparently selective action on the muscles of the back is readily comprehensible.

Forty-two gave a history of obstinate constipation; twenty-two had very marked abdominal pains at irregular intervals; in fifteen of these twenty-two cases, the pains were described as being fairly frequent and severe; in five others the abdominal colic was so severe and so frequent as to cause marked suffering; seven suffered from frequently recurring attacks of diarrhea; nineteen gave a history of a distinct metallic taste in the mouth; twenty gave a history of marked pains and weakness in the arms; forty-two complained of marked pains or weakness in the legs; in eighteen, both the arms and the legs were affected in this way. It is remarkable that in not a single instance was a lead line observed among these printers; only one had a marked deposit of tartar near the margin of the gums. Forty-one of the 109 examined were compelled to wear glasses for ocular defects; in all, eighty-one were found to have defective vision. This marked prevalence of visual defects is quite in accord with the experience of those who have studied the ocular condition of printers. It is quite evident that special study and provisions with respect to lighting is essential in this industry.

In the examination of thousands of working people it has been our experience that the teeth, in a majority, were in a very defective condition. Among these printers, however, it was extremely interesting to note that only seventeen had very defective teeth, indicating, apparently, a degree of attention to the care of the teeth which is quite unusual among those employed in industry, by and large, and seemingly accounting, in large measure, for the absence of the lead line.

Twenty-six of these compositors had defective hearing. This relatively large percentage of cases of defective hearing is worthy of further study with respect to its possible relation to excessive noise from printing presses, etc. Ten had evidence of chronic endocarditis. In addition, there were six cases which showed myocardial affections. In eighteen there was distinct evidence of arteriosclerosis.

No cases of paralysis were found, but, as already indicated, a number of the printers showed very definite weakness in the arms and legs. Thirty-eight had marked tremors. The association of a positive Wassermann test with lead poisoning, which has been suggested by several observers, we were not able to verify in a study of over 400 painters, which I have reported elsewhere; nor could it be corroborated in the study under discussion. Only four of these printers had a positive Wassermann test. In thirty cases we found a marked degree of anemia. Out of a total of ninety-five cases in which the blood was examined, stippling was found in but a single instance. Four persons showed

a fairly marked trace of albumin in the urine; one had casts. So much for an enumeration of miscellaneous findings.

Incidence of Lead Poisoning.—Very strong traces of lead were found in the urine in twenty-two cases; in nineteen cases a moderate trace was found, and in nine a very faint trace; in seventeen a suspicious reaction for lead was obtained, and twenty-two were negative. Altogether, eighty-nine of the printers were tested; the remainder of those examined failed to bring specimens of urine. This test, in accordance with our previous experience, seems to be a very reliable one. In association with the other clinical symptoms, it has been extremely helpful in our determination as to whether an individual was suffering from active lead poisoning, or, whether plumbism was latent, the lead apparently being held in precipitation in the tissues and capable of being dissolved and absorbed as a result of metabolic disturbances, thus causing active manifestations of lead poisoning. In classifying the cases of lead poisoning among printers, we found that twenty-six of them had a number of clinical symptoms characteristic of lead poisoning, together with heavy traces of lead in the urine. Twenty-three others had one or more of the characteristic symptoms of lead poisoning, though not as marked as in the preceding cases, and this group too had evidence of lead in the urine. Two were cases which presented doubtful symptoms. In other words, forty-nine out of 109 compositors, or, roughly, 45 per cent., were suffering from lead poisoning. While in times past there has seemed to be a tendency to focus attention almost exclusively on lead poisoning in the discussion of occupational diseases, it still remains a fact, considering the great variety of industries in which lead is employed, that lead poisoning is a serious problem, as previously stated.

To our great amazement, we found among the union men whom we examined in the course of this study, and who are a well paid and unusually intelligent group, that very few of those who presented serious defects were aware of the existence of these defects. Practically all of them had been examined by physicians at different times for the treatment of various ailments, but the physician's view had been invariably limited to the consideration of the particular complaint which brought the patient to seek his care.

This experience, like so many others of a similar character, confirms one in the belief that there are very many thousands of persons in the city of New York, and in other industrial communities, who are suffering from physical defects or diseases of a more or less serious character, who have no intimation of the state of their health, and who, when they consult their physicians, are studied from a most narrow point of view. This would seem to indicate that we should make a strenuous effort to educate people at large to submit at frequent and regular intervals to thorough medical examination, so that abnormal physical conditions may be discovered in their incipency in order that timely efforts may be made to correct such abnormalities.

INDUSTRIAL DISEASE AND HYGIENE IN THE MEDICAL CURRICULUM

Practically all the medical schools have thus far failed to include in their curriculum the study of industrial hygiene and of occupational diseases. In future years, these institutions will richly merit the reproach

of their graduates because of their blindness in failing to recognize the signs of the times, and the needs of the nearly 40,000,000 persons who are employed in industry in this country. The medical schools of Harvard and the University of Pennsylvania are conspicuous among the very few institutions which devote some measure of attention to the study.

Early this year I was privileged to give what was probably the first formal lecture on industrial hygiene and occupational diseases, to the graduating class of College of Physicians and Surgeons, Columbia University, being required, however, to condense a review of the subject into a one hour lecture. During the past three years, New York University and Bellevue Medical College has given a relatively liberal course on industrial hygiene under the writer's auspices, to its students. Aside from the instances cited, and with possibly one or two other exceptions, so far as I know, all of the prominent medical colleges seem to be oblivious to the existence of industrial hygiene and industrial medicine. The medical clinics which are connected with universities for teaching purposes should utilize to better advantage than they now do, the wealth of clinical material which is available for the study of occupational diseases. Unfortunately, they have thus far virtually neglected this field. The hospitals in this country, with one or two notable exceptions, have likewise neglected the opportunity to study occupational diseases. Is it any wonder then, in view of the fact that the chief institutions of medical learning have failed to appreciate the significance of the occupational factors which influence the development of many diseases, that the private physician's work should reflect this general state of indifference or ignorance?

INSUFFICIENT INFORMATION OF PRIVATE PRACTITIONERS

In connection with the work of the New York Department of Health in the field of industrial hygiene during the period of four years, from the time I organized the work until I was required to relinquish it, a most active campaign had been conducted through various agencies to stimulate, persuade and, if need be, to compel hospitals, dispensaries and private physicians to report cases of occupational diseases which came to their notice. Notwithstanding all these efforts, the total number of cases reported by all the physicians, and by all the hospitals and dispensaries in the city of New York during that time, was virtually negligible. This deficiency was traceable in large part to the lack of proper medical education, and also to the lack of enthusiastic, intelligent and capable medical leadership in this field in New York City. A great opportunity for the study of occupational diseases presents itself to physicians who are employed by various industrial corporations and in connection with whose work a variety of health hazards exist. Already, a number of medical men have won distinction and enriched the literature of industrial hygiene and occupational disease study by their sincere and intelligent efforts in this new field of medicine. On the other hand, the great majority who accept employment as factory physicians are content to conduct what are essentially merely dispensaries for the purpose of rendering emergency service in cases of accidents; too often this work is done exclusively for the purpose of protecting the interests of their employers so far as claims for compensation may be concerned. They fail to see that they have an

opportunity to be of most valuable service not only to their employers, but to the employees as well, and to play the part of pathfinders in this new field of medicine. Unfortunately, they view their "jobs" too often as pot-boilers, and are rarely alive to the rich opportunities which their relation to the factory and its workers affords them. The accompanying table shows the number of cases of occupational diseases reported in New York City, by hospitals and dispensaries, by private physicians and by the Public Service Commission, respectively.

FOUR YEARS' RECORD OF OCCUPATIONAL DISEASES

	Reported by Hospitals, Etc., Cases	By Physicians Cases	Public Service Commission Cases
1915	5	6	0
1916	53	13	0
1917	42	49	39*
1918	32	12	107*
Total	132	80	146

* Caisson disease.

The table shows that in spite of four years of intensive effort to bring home to physicians and institutions which care for the sick in New York City an appreciation of the importance of reporting all cases of occupational disease, we obtained a total number of 212 reports during the four years, from both sources. In connection with the excavation and construction of tunnels for the extension of the city's subway system, the physicians employed by the Public Service Commission reported, during 1917 and 1918, 146 moderately severe cases of caisson disease. Mild cases of caisson disease occurred which escaped detection or which were not reported. Excluding the cases reported by the Public Service Commission, it must be obvious that only an absurdly small fraction of the grave occupational diseases occurring among the several hundred thousand workers in our city are correctly diagnosed and recorded through the formal reports of institutions and private physicians.

OPPORTUNITIES OF HEALTH OFFICERS

The various federal, state and municipal health bureaus have opportunities for helpful research and educational activities in the development of proper supervision of the health of factory workers for the purpose of detecting and preventing diseases which are directly or indirectly due to industry. The officers of the U. S. Public Health Service and of the Department of Labor have made substantial and valuable contributions to industrial hygienic studies and to the study of occupational diseases. Schereschewsky, Alice Hamilton and others have done conspicuous service in this field.

The cooperation of the various agencies which are interested in industrial hygiene, with manufacturers' associations and with labor unions, needs greatly to be developed. Hospital and dispensary staffs and private physicians need to be brought to a keener appreciation of the great service which they can perform to society, as well as to medical science, by training and equipping themselves to recognize those diseases which are the direct and specific sequelae of occupation, and also the great number of diseases in which occupational factors play a more or less significant part. Not only will they thus add to the store of medical knowledge, improve

the efficiency of industry and preserve the health of working people, but they will also serve to reduce the enormous casualties from preventable diseases suffered annually by workers in industry, and lay the foundation for constructive, sane and helpful legislation. In only a few instances have state or municipal health officers included the subject of industrial hygiene and the prevention of occupational diseases in their health programs. They have failed up to the present to perceive how closely related industrial hygienic work is to the prevention of tuberculosis, pneumonia and the degenerative diseases.

Here and there, with very few exceptions, the state labor departments have given nominal and usually inadequate attention to industrial hygiene and the prevention of occupational diseases. All too frequently, when labor and health departments in any given community divide responsibility for this work, the effectiveness of their efforts has been marred by petty jealousies and conflicts as to authority. The state and local health officers are offered great opportunities in this new field of preventive medicine, not only because they enjoy the right of access to factories, but also because, in addition to conducting research as to influences affecting the health of workers, they have the power to enact and enforce laws to create proper sanitary conditions in the industrial environment, and to prevent diseases directly or indirectly due to occupation.

The labor unions, one would judge, would be keenly alert to the value of conserving the most precious asset of working people, namely, health. The earning capacity and the general welfare of the worker and of his family are so largely dependent on the maintenance of good health that one would quite logically expect intelligent labor groups to be the most ardent supporters of public officials who are charged with the responsibility of conserving the health of workers. Unfortunately, labor representatives in this country, generally speaking, have not manifested an understanding of the vital significance of health conservation to the welfare of the worker.

During a period of four years recently ended, I was fortunate in obtaining the support of a number of intelligent labor leaders in the city of New York, in furthering a program for effective work in the field of industrial hygiene. Through the cooperation of certain progressive labor leaders, the four central or chief labor organizations of the city, together with more than 100 subordinate labor unions, were organized by me to constitute the Labor Sanitation Conference, serving as a vigilance committee. It was through the efforts of this labor sanitation conference that the \$20,000 originally allowed for industrial hygiene work, in 1915, was increased by an additional appropriation of \$63,000 per annum.

Taking the country by and large, there is little evidence that labor organizations have even begun to appreciate that the campaign for the protection of the health of those in industry is quite as vital to their interests as better wages and shorter hours, to the procurement of which they have thus far limited practically all their efforts.

FUTURE DEVELOPMENT OF EFFORTS

In the hasty sketch which has been offered, I consciously and deliberately have attempted to picture the

subject of industrial hygiene and occupational diseases as a practically undeveloped field of preventive medicine, still in a crude and formative state. The allusion to the shortcomings of medical colleges, of hospitals and dispensaries, of industrial and general practitioners and of health officers and others, so far as concerns their lack of sympathy and support of an aggressive campaign to develop industrial hygiene and the prevention of vocational diseases, was also deliberate. The health, vitality and well-being of millions of workers, as also the stability and welfare of their families, and of the nation as a whole, depend on the recognition by the medical profession of the significance of industrial hygiene as a part of preventive medicine. The emphasis which I desire to place on the inadequacy and faults of the present system of medical education, and of the methods for safeguarding the health of working people, is not intended as ungenerous criticism of the agencies already existing, which are concerned in the formulation and execution of a well developed program looking to this end. These criticisms are offered in the hope that in a measure they will help to hasten the day when state and city officials who are jointly responsible for the protection of the health of workers will lay aside their petty personal differences and jealousies to devote themselves exclusively to the solemn and serious duty of guarding the public health.

Expert, socially minded, conscientious and efficient health officials are urgently needed for the proper development of this type of work. They must come to feel secure in their tenure of office, as a result of the support of a public educated to appreciate the overwhelming importance of the conservation of human life. There must be team work among the state, municipal and federal officers. Nor should political considerations be permitted to dwarf the size of appropriations for work necessary to prevent the occurrence of occupational as well as of other preventable diseases. A nation that is rich enough in times of peace to expend enormous sums for improvements of rivers, harbors and postoffices, which have little justification except as sops to local pride and local interest, and, further, a nation which gives millions annually for the conservation of cattle and hogs, and which is ready, if need be, to expend millions daily for the purposes of war, should be brought as soon as possible to appreciate the transcendent importance of expenditures to conserve human life and human happiness, which are so dependent on health.

Although there have been recent signs that those interested in the development of industrial hygiene are coming into more intimate relations with each other, as testified to by the interlocking and improvement of the work done in this field by the U. S. Public Health Service and the U. S. Department of Labor, there exists still a most urgent need of a partnership of the latter two departments with the respective state and city officials responsible for the supervision of conditions in industry. At present there is too often overlapping, duplication, and even conflict between various agencies who subdivide part of this work among themselves. There is also a lack of authoritative leadership. At times one agency repeats the work already completed by some one else, without knowing that it is subjecting employers and employees to needless trouble and interruption from work. A clearing house

for official workers in industrial hygiene is most urgently needed. The U. S. Public Health Service would seem to be the logical leader to serve as clearing house, guide, and bureau of information, in the absence of a national department of health. It must be manifest, from what has already been said, that the future development of industrial hygiene and medicine hinges also on a reform of the curriculum of the respective medical schools, on the sympathy and willingness of private physicians and hospitals to aid in protecting the public welfare by equipping themselves for the recognition of occupational diseases, and by bringing to light cases coming to their attention, in order to show their relative frequency and importance as a cause of morbidity and mortality.

Employers must be instructed and advised so that they will come to prize the watchful supervision of their employees by physicians quite as much as they value the frequent inspection of their machinery by the competent engineer. It must be shown that industrial hygiene not only serves as a humane work conducive to better relations, but also adds immeasurably to the efficient operation of a factory or other industrial establishment. Workers must be taught to value the preservation of their health as a precious asset from the standpoint of earning power, and also from the point of view that good health is the best and most necessary form of insurance which they can provide for their families against dependency and want.

ABSTRACT OF DISCUSSION

DR. FREDERICK LEE, New York: One matter of which Dr. Harris has spoken has interested me especially. He has mentioned two instances of poisoning by poisonous gases, one where a number of workers were more or less overcome by carbon monoxid, and the other where workers were overcome by carbon dioxide. This brings out one of the important factors which needs to be developed in the study of fatigue and that is the question of ventilation. I wish to cite an instance which has been brought forward, but not yet published, by Dr. Vernon of Oxford. Dr. Vernon investigated certain operations in the tinplate industry and found that the health of the workers varied inversely with the temperature of the outside air; the output of August was 10 per cent. less than the output of January. The highest output occurred in January, when the temperature was lowest. The lowest output occurred in August when the temperature was highest. He found at the same time that this seasonal variation was largely overcome by proper ventilation of the workrooms.

Muscular Tonus in Relation to Fatigue.—In subjects doing relatively strenuous work during the day, or where long hours were being spent in work, there was usually a decrease in the tonus in the evening as compared with the morning condition. This was more pronounced when the subject was losing rest (sleep). After lost rest the morning tonus was lower and the average tonus for the day was less than on days following a good night's sleep. Evidence was thus obtained of cumulative fatigue effects. Sleep at night or during the day was usually followed by a considerable increase in tonus. Strenuous work of short duration was usually followed by an immediate decrease in tonus. Psychic influences (excitement) seemed occasionally to produce an increase in tonus, although fatigue-producing conditions were recorded in the history. In subjects doing relatively light work and obtaining plenty of sleep the tonus varied during the day, the evening tonus being frequently greater than that observed in the morning. (*Pub. Health Rep.* 34:1622 (July 25) 1919.)

THE INFLUENZA EPIDEMIC AND ITS AFTER-EFFECTS IN THE CITY OF BUFFALO

A DETAILED SURVEY*

FRANKLIN C. GRAM, M.D.,

Acting Health Commissioner

BUFFALO

Epidemic influenza struck Buffalo with the suddenness of a cyclone. During September, 1918, we had thirty-three cases. October 1, the disease manifested its presence with twenty-one reported cases, and, by October 14, we had the highest number reported in one day, namely, 1,886 cases, with forty-eight deaths from influenza, seven from pneumonia and seven from bronchopneumonia, making a total of sixty-two deaths in one day. This was the peak in the number of reported cases for a single day; after it a gradual decline became perceptible. The highest number of deaths occurred, October 19, with eighty-five from influenza, eighteen from pneumonia and nine from

TABLE 1.—SUMMARY OF CASES AND DEATHS IN BUFFALO

Grand total.....	33,813

bronchopneumonia, or a total of 112 deaths for a single day. The total number of cases for October was 23,544; in November and December there were 1,846 and 2,975 cases, respectively, making a total of 29,398 cases from September to December inclusive, with a total of 2,561 deaths for the same period from influenza, pneumonia and bronchopneumonia.

January showed a considerable increase, with 4,053 cases of influenza, 140 of pneumonia and 109 of bronchopneumonia. There were 249 deaths from influenza, fifty-eight from pneumonia and eighty-one from bronchopneumonia, making a total of 388 deaths. In February the number of cases declined to 813, and in March they came down to 187.

SEPARATION OF INFLUENZA AND PNEUMONIA

Buffalo, in common with other cities, suffered for the want of physicians and nurses when the influenza epidemic struck us in October. Physicians were so overwhelmed with work that it was a physical impossibility to see most of the patients more than once. For this reason, physicians often failed to differentiate between influenza and pneumonia, but reported all cases as influenza. It was only the severest or fatal

* Read before the Section on Preventive Medicine and Public Health at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

case which received more careful attention and diagnostic accuracy; hence our early reports were complete only in our mortality statistics, and it was not until the crest of the epidemic wave had passed that anything like accuracy in morbidity statistics was possible.

MEASURES EMPLOYED

Verification of Statistics.—Much has been said and written about the inaccuracy of morbidity statistics relative to influenza. When Buffalo found itself in the throes of the disease, the mayor of the city, on the advice of the acting health commissioner, issued a proclamation closing all theaters, moving picture shows, churches, Sunday schools, public schools, parochial schools, private schools, saloons and dance halls, prohibiting, in fact, all indoor gatherings. This proclamation was in force exactly three weeks to the day.

Fortunately, a street car strike occurred during practically the same period. I am satisfied that the drastic proclamation and the street car strike were responsible more than any other measures for the comparatively low morbidity in Buffalo, that being less than 7 per cent.

Organization of Schoolteachers.—By closing the schools, over 2,000 teachers in public schools became idle. Here was an opportunity which I immediately made use of by organizing them and making a house-to-house canvass of the entire city by districts.

With 2,000 teachers at my command I was enabled to accomplish much which otherwise would have remained an impossibility. First, I was enabled to check up the reported cases. As a result of this comparison I found that fully 95 per cent. of all the cases were reported, the remaining 5 per cent. being practically those in which the patients were only slightly ill, therefore deeming it unnecessary to call a physician, or those in which, for some reason or other, it had been impossible to obtain a physician. Second, patients who were seriously ill and unable to obtain a physician were immediately sent to the hospital, in some instances entire families being cared for by sending the sick member to the hospital and the contacts to a temporary isolation hospital. Third, I was enabled to do a great deal of social service by providing food, fuel or other necessities wherever required.

Hospital Facilities.—During the early part of October, a large high school building in the center of the city was quickly converted into a temporary hospital. Another building was used as an isolation hospital for contacts, and a third as a convalescent hospital for such patients as had recovered from the disease but who were unable to return home, or who had no home and were unable to work; or for the many others who were without means and therefore unable to pay for board and lodging. Each one of these three classes was quite large, and the service performed was of the utmost value.

Red Cross Motor Corps.—No report of the influenza epidemic would be complete without special mention of the ambulance service which was organized by the girls' motor corps of the Buffalo chapter of the Red Cross. These young ladies not only drove ambulances, but many their private cars, from long before dawn until far into the night, answering calls, carrying the patients on stretchers from the homes into the ambulances, and again into the hospital, often putting them to bed.

A noteworthy incident is that, as far as is known, not a single motor corps girl contracted the disease.

INFLUENZA AND ITS SEQUELAE

Duration of the Disease.—Our influenza was like a prairie fire—short and drastic. Every influenza patient was either convalescent or dead within five days from the onset of the attack.

Sequelae.—A characteristic of the acute infectious maladies is their proneness to leave certain after-effects, and while the particular conditions liable to follow the principal maladies are generally known, much remains unknown, particularly as regards the determining factors, individual susceptibility and the extent to which each after-effect may be anticipated in a given epidemic visitation.

Influenza is one of the most serious of the infectious diseases, and is capable of exerting its fury on many of the vital systems of the body, so that a wide range of after-effects may be observed. Notwithstanding, it is noteworthy that exact knowledge and data concerning all that pertains to these sequelae are wanting. Writers speak of tuberculosis and bronchial affections, nervous affections, serious affections of the eye and ear, a disposition to awaken latent maladies and create a predisposition to others as among the sequelae, but they do not furnish information as to the ratio of these sequelae to the whole, or of the particular influences that determine them, all of which can have a practical bearing, both in prevention and in general treatment.

The epidemic of 1889 and 1890 showed that the greatest number of deaths did not occur in association with the attack itself, but rather in the following two years, the explanation being that the malady left undermining conditions, weaknesses and lessened resistance, thus rendering the individual vulnerable to subsequent ailments proving fatal.

From this it would appear that the general condition in which the individual is left immediately following the attack is of much importance, the subsequent element of time permitting valuable reconstructive treatment.

THE SURVEY

With the fact in mind that probably no investigation of the numerical relations between the malady and its sequelae had ever been made, and that the findings of the epidemic of 1889 and 1890 showed time to be an important asset in postinfluenzal conditions, I determined to institute a survey of the recent epidemic in Buffalo to ascertain the percentage of sequelae, and, incidentally, to gather such other data as appeared pertinent, and, finally, to secure reconstructive treatment where indicated.

Dr. Herman M. Biggs,¹ health commissioner of the state of New York, said:

In the last great epidemic of 1890, 1891 and 1892, the greatest mortality occurred in 1891, the second year, although all three of these years showed a larger death rate from the acute respiratory diseases in New York City than had been experienced before for many years. It is not possible to assess even approximately the extent of the loss which influenza has brought and will bring to the country. On the sickness and the death rate we find its malign influence. The present indications would seem to show quite clearly that the deaths from influenza and its complications in the United States during the present year will probably exceed 300,000.

1. Biggs, Herman M., Review of Reviews, February, 1919.

The *Survey* of Feb. 22, 1919, contains the following:

The Metropolitan Life Insurance Company made a study of its experience among industrial policies following the epidemic of 1889. The results show that the greatest number of deaths from pneumonia and all causes did not fall in the epidemic year, but in the years following—most heavily from 1891 to 1893; in other words, that the patient who survived the flu was weakened and was carried off by some subsequent illness.

Immediately after the pandemic subsided, I endeavored to determine these conditions in Buffalo by an actual investigation. If we had as a result of influenza a larger number of our people suffering from tuberculosis, heart troubles or other organic diseases, we should by so locating them immediately learn whether they were being cared for by their own physicians and at a time when treatment might be most effective, and if, for any reason, they were not receiving proper attention, we could assist in securing whatever medical or other aid was needed.

With that object in view, I had follow-up cards printed containing the names and addresses of every influenza victim since October 1. I directed the physicians, nurses and inspectors who are regularly employed in the various bureaus of the department of health to take a certain number of cards with them on their daily inspections and attend to this additional work. After about six weeks of effort, only approximately 8,000 such calls had been made, and it became apparent that this method would take too long, and that, if the information relative to influenza victims was to be of any service, it must be had within a shorter time.

I therefore appealed to the mayor and to the city council for a sufficient appropriation to employ extra help and make the investigation immediately. This authority was granted. The field work was done by extra inspectors appointed for the purpose, and paid for by the emergency appropriation. They were given the cards containing the names and addresses of the patients, and instructed to obtain answers to all the questions contained thereon.

These printed cards, used by the canvassers for their field investigations in obtaining an after-influenza record, contained the following:

Name of patient. Address. Number in family. Was father ill? Was mother ill? What other members were ill (giving names and ages)? Are all patients fully recovered? If not recovered, give particulars. Any deaths (give names)? Name of attending physician. Does family need: (1) medical or nursing care, (2) relief or other assistance? Housing. Number of rooms. Sanitation. Special remarks.

This covered the information required for the crude field work. The details were accomplished through subsequent visits by medical inspectors from the department, or by telephone communication with the attending physician.

The city was divided into districts, and an inspector was assigned to ascertain from each person in his own words whether his recovery had been "complete," or, if not, to what his impairment was due, as learned from his attending physician. Those reported as recovered and again performing their usual occupations were immediately classified as such. All patients whose conditions could be considered as properly associated and worthy of scrutiny as to their nature and ultimate possibilities were referred and made subjects of direct communication with the attending physician; if no

physician had been in attendance, a physician from the health department was detailed to investigate. Thus, a complete survey was made of all who had had the disease, and, when recovery was not complete, further investigation was pursued in those cases in which it was deemed proper.

The difficulties attending such work are not slight. Individuals are frequently not responsive and resent interference, so that much tact is essential.

The field work occupied a period of approximately two months, but the cards were compiled daily, and cases requiring medical or other aid received immediate attention. In Table 2 are shown the extent and the results of the survey.

TABLE 2.—RESULTS OF THE SURVEY

Total cases of influenza and pneumonia reported from Oct. 1, 1918, to March 31, 1919	33,880
Number of calls made by physicians, nurses and inspectors (without covering) of the department of health	8,000
Number of calls made by extra canvassers and inspectors	17,699
Total calls	25,699
Total deaths from influenza (October to March, inclusive)	2,248
Deaths from pneumonia	538
Deaths from bronchopneumonia	403
Total deaths from these three causes (October to March, inclusive)	3,179
Recovered	28,663
Not located (changed residence)	1,290
Patients not fully recovered	748
Total cases	33,880

* These 25,699 calls covered the 33,880 cases, some families having more than one case.

The character and the number of the sequelae occurring in 748 cases, as disclosed by this survey, are shown in Table 3.

TABLE 3.—CLASSIFICATION OF THE SEQUELAE

SUMMARY

1. A final, detailed analysis, carried out as far as possible to the present time, is exceedingly gratifying, showing that out of 748 cases found on the first examination to have some form of sequelae, 501 patients have since recovered, and 216 are reported as improving. The nature of the reports indicate that practically all of the 216 will, in the near future, likewise be discharged as recovered.

The four deaths reported since the primary investigation may or may not have been due to influenza sequelae. The question is debatable both ways, as no one can say that in the natural course of events the patients would not have died even if they never had had influenza. Only one death out of the four was caused by tuberculosis, and the history of this case was such that, although not a reported case prior to the influenza epidemic, there is a strong probability, according to the history given, that the patient was already suffering from tuberculosis before he contracted influenza.

This brings us down to what, by many health authorities, is considered the most important definite knowledge for practical purposes, that pertaining to the twenty-seven cases of tuberculosis. Out of this number eleven were already on our records as reported cases of tuberculosis before the influenza epidemic began, and must therefore be eliminated from the number which could possibly be charged to influenza.

Eight cases still classed as suspected tuberculosis are under present observation, with no definite diagnosis.

This leaves only eight cases reported since the epidemic of tuberculosis among patients who had influenza, and several of these were in families with a tuberculous record.

2. This survey definitely established the entire after-influenza situation in Buffalo.

3. With more than 2,000 public school teachers at our command for a house-to-house canvass, we established the fact during the influenza epidemic that practically all influenza cases in the city of Buffalo were reported.

4. So far as is known, no other city in the country made a similar canvass during the epidemic, or a similar after-influenza survey.

5. Every possible care was exercised to make both the canvass and the survey as accurate as possible. Both were made by dependable persons. We cross-checked the records. Reexaminations and subsequent visits were made until the status of every case was definitely decided.

6. The fact that only twenty persons who had had influenza required immediate assistance from the superintendent of the poor speaks well for the residents of Buffalo.

7. It is shown that the number of sequelae are relatively smaller than anticipated and that their character was generally not as severe as indicated in many statements issued.

8. The first important observation is the small number of sequelae. As stated, with a morbidity of such capacity, a greater number would be anticipated.

9. In contradistinction to observations relative to previous epidemics, I do not anticipate any serious results among the persons who had influenza in Buffalo and recovered. Our mortality appears associated and not deferred.

10. While our mortality rate from influenza and pneumonia was large, our morbidity rate was relatively small, being less than 7 per cent.

11. One fact is definitely established, and that is that we have nothing to fear from tuberculosis as a sequel to influenza in Buffalo. I do not consider eight cases with a definite diagnosis of tuberculosis more than we would ordinarily look for among 33,880 individuals.

12. I believe the same may be said of the other cases classed as "improving." This number also is not larger than that which would ordinarily be expected with some organic trouble among so large a number of individuals.

13. The salient features presented by this survey show:

(a) The small number of sequel relative to the whole number of influenza cases.

(b) Their character, at variance, in general, with the type of sequel and consequences as recorded by most writers.

(c) The high percentage of recovery after a period of several months, and the nondevelopment of any considerable number of intercurrent affections, which are apprehended and most prone to develop.

(d) The frequent sequel of mild eye, ear and throat affections—100 cases in 748, or about one in seven; and the high percentage of recoveries without permanent after-results.

(e) The demonstration, by results, of the value of early and vigorous preventive measures, such as publicity regarding the necessity for personal and general

hygiene; the closing of schools, churches, theaters, saloons, and, in fact, prohibition of every public assemblage or gathering of more than ten persons; the wearing of masks; the use of prophylactic vaccines; the organized facilities and provision for hospital care and treatment; the care and isolation of contacts, and the care of convalescents in suitable convalescent homes or hospitals, and at public expense when necessary.

(f) Few cases of sequel affecting the alimentary system (the affections which occurred being of the stomach, and not intestinal).

14. Credit for this showing properly belongs to the Buffalo Department of Health, backed by the mayor and council, for their prompt, aggressive, vigorous and unrelenting measures, instituted at the beginning and maintained throughout the course of the influenza epidemic.

ABSTRACT OF DISCUSSION

DR. A. LEO FRANKLIN, Cumberland, Md.: I wish to ask Dr. Gram whether we understood him correctly that out of the total of 28,000 recovered patients, examinations were actually made on approximately 748?

DR. FRANKLIN C. GRAM, Buffalo: No. Every case that was reported was examined. The cases of recovery were immediately eliminated, leaving only 748 for special investigation.

DR. FRANKLIN: In other words, it was estimated that no examination was made of those that recovered completely.

DR. GRAM: That is the effect of it.

DR. FRANKLIN: If that is the case, I fear that we might possibly go astray if we were to assume from the comparatively limited number of patients who were reexamined, that they were not affected in one way or another by the after-effects of influenza. The experiment made in Buffalo would have been much more valuable if it had been possible to take several thousand of these apparently recovered patients and apply a careful medical examination to ascertain whether there were any after-effects. In Boston, an examination of that kind indicated there were decided after-effects. Similar studies have been made in other cities which seem to give the same results. Similar discoveries are being reported by medical practitioners. There is nothing at the present time that we need to be so careful of as these after-effects of influenza. After the epidemic of 1889 there was a continued high mortality, and it was not until approximately five years afterward that the general mortality of such cities as Philadelphia, New York, Chicago and Boston got back to the normal. Whether this is due to influenza, no one is in a position to say, but I believe we ought to be exceedingly careful at this time not to draw any conclusion not warranted by the facts, and furthermore, it is necessary, in my opinion, to make an exceedingly intensive study in certain communities to determine whether influenza is leaving these after-effects or not.

DR. E. B. FISCHER, Chicago: In October, 1918, at the height of the influenza epidemic in Chicago, the physicians and nurses in the eight dispensaries comprising the field department of the Chicago Municipal Tuberculosis Sanitarium were directed by the commissioner of health to discontinue the regular tuberculosis work and take care of the non-tuberculous as well as the patients registered with the dispensaries. We were impressed with the fact that of about 3,500 patients registered at our dispensary, only thirteen were referred to us with influenza. This observation was corroborated by the dispensary physicians in the other districts and as a result a survey was ordered of these cases. Out of 8,500 patients treated, we had fifty-one patients who were registered with the dispensaries; an incidence of about 0.6 per cent. In the Cook County Hospital and in Oak Forest, where advanced cases of tuberculosis are treated, eighty-five cases of influenza were found among 1,551 persons; an incidence of 5.4 per cent. Based on these observations, we concluded that individuals with active tuberculosis had a diminished

susceptibility to the influenza infection. On the other hand, in the past six months we have observed in our dispensary clinics, almost daily, moderately advanced and advanced cases of tuberculosis with a history dating back to an influenza attack in the past year. We concluded from our clinical observation at the dispensaries that individuals with latent tuberculosis may have their conditions aggravated by the influenza infection. The attendance at our dispensary clinics has increased largely due to the influenza epidemic on account of respiratory complications following in the wake of the epidemic and on account of the active campaign now being carried on against tuberculosis in our city.

DR. B. R. WAKEMAN, Hornell, N. Y.: In Hornell, a city of 15,000 people, 2890 cases of influenza were reported during the epidemic of October and November, 1918. Early in January we made a postinfluenza survey. Out of this number 700 persons had not fully recovered. Nearly 400 were examined in the clinic by the superintendent of the county tuberculosis hospital, an expert diagnostician. Forty persons were found to have tuberculosis. From January 1 to October 1, 1918, only two cases of tuberculosis had been reported to the health officer. The postinfluenza survey had so stimulated the interest of the community that over fifty cases of tuberculosis have been reported since October 1, 1918. The epidemic possibly may not have reactivated all of these cases of tuberculosis, and this increase may have been due, to a slight extent, to the campaign of publicity. Nevertheless, my personal opinion is that influenza in our locality has materially increased our cases of tuberculosis.

SIR ARTHUR NEWSHOLME, London, England: Influenza was the reason for much critical newspaper publicity of public health possibilities both in England and in America. One has to realize the importance of public health authorities in facing this lane. In England it was stated that we could get no farther unless we had a minister of health and placed in his hands the machinery for handling influenza! We remain almost helpless in the prevention of acute respiratory diseases in contrast with our control over such diseases as typhus, enteric fever, diphtheria and also tuberculosis. We may hope that with the extensive pathologic and epidemiologic investigations now being pursued, we shall in a few years be able to place these acute respiratory infections on our list of preventable diseases, but we have no immediate hope of this being realized. I was interested in what was said about the relation between tuberculosis and influenza. So far as our national statistics in England are concerned, every year showing an excessive death rate from influenza, has been followed by a year in which the death rate from tuberculosis has been excessive. Many deaths from tuberculosis are undoubtedly hastened during an epidemic of influenza. I was interested in the statement that influenza has been actively present since 1889. Has this been so? Is the recent outbreak the same influenza that we have had each year, or is it another influenza? Do we at intervals from some unknown source obtain a more virulent influenza, or is it an old influenza, which has become more virulent under conditions of which we are at present totally ignorant? That is the problem. It may be one or the other, but the rapidity with which the more virulent influenza spread right through the civilized world under war conditions no doubt facilitated by the immense increase in facilities for conveyance, is one of the most striking things in the medical history of the world. It seems to me that unless medical science is able to prevent ordinary catarrhs and to prevent them from becoming something more serious, it is unlikely that we shall be able to control influenza epidemics.

DR. YUORC C. VARGAS, Ann Arbor, Mich.: As Sir Arthur has said, it is still a question whether endemic and virulent influenza are one and the same thing, varying only in degree of virulence. I am collecting data bearing on this matter and I have one or two things that apparently bear strongly in one direction. In many camps in this country in March and April, 1918, we had typical influenza. It came suddenly, lasted for a few days, and disappeared as quickly as it came. Such an epidemic at Camp Forrest was ably studied and reported at the time by Major Soper. At another camp at

Hattiesburg, Miss., there was in April a division of troops numbering about 26,000. An epidemic of mild influenza struck this camp in April, 1918, and within ten days there were about 2,000 cases. This included not only those who were sent to the hospitals but also those who were cared for in barracks. This was the only division that remained in this country without change of station from April until the fall of 1918. During the summer this camp received 20,000 recruits. In October, 1918, the virulent form of influenza struck this camp. It confined itself almost exclusively to the recruits of the summer and scarcely touched the men who had lived through the epidemic of April. Not only the 2,000 who had the disease in April but the 24,000 who apparently were not affected escaped the fall epidemic. It appears from this that the mild influenza of April gave a marked degree of immunity against the virulent form in October. There is another observation which points the same way. Looking over the statistics of the fall epidemic in cities in the United States we find that certain cities had a low death rate, while others had a relatively high death rate. Among these cities which had a low death rate we will mention Atlanta, Ga.; Kansas City, Mo.; Detroit, Mich., and Columbus, Ohio. Going to the spring records of these cities we find that in all of them in March and April of 1918 there was an unusually high death rate from pneumonia and undoubtedly in these cities at that time there was a relatively mild epidemic of influenza. In this way I am inclined to account for the relatively low death rate in these cities in the fall of 1918. I make no claim that this and other instances of a similar kind prove that the mild and virulent forms of influenza are manifestations of the same disease, but I do hold that the evidence points that way. I want to call attention to the fact that sanitation, as we ordinarily understand it, had no influence on the prevalence or the death rate from influenza.

DR. WILFRED H. KELLOGG, San Francisco: I want to call attention to a very significant fact, which is, that the mortality statistics for the last five years show a very rapid increase in deaths ascribed to influenza. I first noticed in the figures for California that for every succeeding year during this period the reported mortality from influenza has increased. The reported deaths from influenza have jumped to almost double for each year for a period of five years and I observe that this is true also of the reports of the United States Census Bureau for the registration area. Now, this suggestion: That our influenza epidemic was not due to the importation of a virulent strain from Europe but was due to an increase in virulence which was simultaneous throughout the world.

DR. H. D. WOOD, Providence, R. I.: It may not be generally known that during the summer of 1917 there was a streptococcal sore throat going throughout the army. We had it in the West Virginia camps, and they were sent from there into Ohio, Maryland, Virginia and elsewhere. There was no influenza, no respiratory conditions, except the spitting of blood, but the hemolytic streptococcal sore throat spread throughout the United States.

DR. L. I. DUBLIN, New York: We have been for some time engaged in analyzing the returns concerning our company, and it may be of some interest to give you knowledge concerning the preliminary finding. They will point, I think, very significantly to some conclusions. In the first place, we find in regard to this disease, from the mortality returns, that the heaviest instances of the disease are localized, the death rate experience. This experience includes some twelve millions concerning whom we know a great deal. We find from the curve that these increases in mortality rates from the epidemic of influenza and pneumonia are localized in the ages 15 to 50, getting at their height at the ages 25 to 29. That is true not only for the industrial, but the intermediate and the ordinary groups which represent millions of policyholders, affecting one, the same in all three groups, but varying somewhat in the height of the curve. Then, we find a very marked difference in the sexes, 25 or 30 per cent. in favor of the females. Then, there is a marked difference in races. The colored people show a very much lower mortality rate at these same age periods than do the white people. Of

course, the curve was the same; the peak was between 25 and 29. There are certain age periods where the effect was virtually negligible, at the age of 50, but at the height of the curve, from 15 to 50, the rate was conspicuously lower for the colored than for the white race. There is also a localized incidence, highest for the males, for the white males, and also localized at from 15 to 50 years of age. Finally, the highest instances are observed along the Atlantic seaboard; that as we go inward, into the interior, we find a lessening of virulence as indicated by the death rate, being lowest as we approach the Pacific coast, with one exception, and that we do not understand. That is San Francisco. It is quite possible, however, that in that city we are concerned with a double infection, that is, one coming from the East and being of a small caliber, and the other coming by way of the Panama Canal, or perhaps from Asia, because the period of highest incidence in San Francisco as in a few other places on that coast, where the figures are available, was the highest curve, and several weeks in advance of interior points. It is, therefore, quite possible that the infection was brought in in two different ways.

DR. CHARLES J. HASTINGS, Toronto: Soon after the declaration of the war that we have just passed through there was a very valuable and significant pamphlet published and circulated broadcast throughout the country, entitled "Know Your Enemy." I think that we had better recognize the importance of this and acknowledge the fact as promptly as possible, that we do not know our enemy in the pandemic we have just passed through. Various organisms have been found present, and numerous strains of each, and there have been cases where they have all three been present and where one only has been present. So that we are not justified in saying that any one of them is the cause of the disease. This being the case, we must assume that we do not know what is the cause of this disease. It may possibly have been a malignant form of the mild influenza of former years. I am sorry to learn that there are yet a few who have some faith in vaccines, and who claim to have had wonderful results from their use. That there is a tremendous amount of virtue in vaccines cannot be doubted, but how can we claim to have a valuable vaccine when we do not know what we are preparing it for? Until we know the organisms that cause the disease, we cannot hope to have an efficient vaccine. We must recognize the fact that vaccine is along the right line. We hope that a vaccine will be perfected and will have the desired results, but do not let us continue to claim that we have an efficient vaccine at present, which I am satisfied we have not.

DR. FRANKLIN C. GRAM, Buffalo: It would be impossible to cover the many points alluded to, but I want to refer to the one that Dr. Frankel presented. We had to eliminate, for the present survey, all those who were found to be recovered and who had returned to their work. A survey of this kind is extremely difficult to make, even at best. When you go to a home, and they tell you that the patient has recovered and has returned to work, it is a difficult problem to follow that case up, as most people resent interference; this is aggravated when you have about 33,000 cases to deal with; for that reason we confined our efforts principally to those who had some form of sequel. The present mortality has been alluded to as being increasing, but in Buffalo it is down to normal. Of course, it is impossible to say what the future will produce.

Effect of Hunger on Moral Qualities of Germans.—A rather important factor is the effect of hunger on the moral qualities. The entire population is suffering from the effects of the food situation. I have been able to observe this among my assistants at the university. Their efficiency, both mental and physical, has decreased. Their mood is one of deep depression, lack of inclination to work, and lack of energy. In the case of many persons, especially among the lower classes, there is observable an inordinate longing for amusement, a phenomenon which we have in former times been able to observe in history during periods of plagues and pestilence. People saw death before their very eyes.—Dr. MAX RUTNER

THE FAILURE OF SURGERY ON THE
EXTRAHEPATIC BILIARY PASSAGES

AN ANATOMICOClinical CONSIDERATION *

MOSES BEHREND, M.D.

PHILADELPHIA

Before considering the anatomy of the structures in the region of the foramen of Winslow, it may be profitable to study the relation of the peritoneal bands

usually due to the raw surfaces left. If these bands continue as part of the lesser omentum, one can readily see distinct blood vessels coursing through the fine network of peritoneal tissue, which require ligation after their severance. While it is true that many bands seen at operation are undoubtedly newly formed adhesions due to a previous inflammatory process, there are about 20 per cent. of cases in which the bands are embryologic structures. Flint and others have ascribed them to the rotation of the cecum from its hepatic position. This view is supported by the fact that these bands of

Fig. 2.—Peritoneal band from gallbladder to duodenum and lesser peritoneum; not an inflammatory adhesion.

Fig. 3.—Peritoneal band from gallbladder to the transverse colon; not an inflammatory adhesion.

Fig. 5.—Large fan-shaped peritoneal band from gallbladder to stomach and duodenum. Note how the gallbladder is covered.

and adhesions found in this region to the gallbladder, ducts and blood vessels to the surrounding organs and hollow viscera. It is a matter of some importance to decide whether these folds which extend from the gallbladder to the hollow viscera and the great omentum are really inflammatory in character, or whether they

peritoneum have been repeatedly found in the fetus and in infants, in whom the opportunity for an inflammatory lesion to be the cause is practically unknown.

There are advocates on both sides of the question. Such men as C. H. Mayo and J. M. Flint¹ consider these bands to be developmental in character, while

Fig. 6.—Broad peritoneal band from gallbladder due to the fetus and great omentum.

Fig. 7.—Fan-shaped band from gallbladder to the great omentum.

Fig. 11.—The cystic artery and duct in their proper relation. The cystic artery runs under the hepatic duct.

are simply developmental embryonic structures. The differentiation is important at operation. Adhesions usually are of denser texture, they are not so easily separated, and usually in themselves they are devoid of blood vessels which require ligation. The bleeding which occurs after adhesions have been separated is

Deaver and Coffey adhere to the other view. I agree with Mayo and Flint that these bands are not all inflammatory. I have reached this conclusion after a careful study clinically and in the laboratory. At operation we speak of these bands as adhesions. Symptomatically these peritoneal bands may give rise to the same pathologic condition as that produced by true adhesions. The treatment will necessarily be the same; the bands must be divided, the organs made more

* Read before the Philadelphia County Medical Society, May 28, 1919.

¹ Owing to lack of space, this article is abbreviated in this Journal. By the inclusion of several illustrations. The complete article appears in the author's papers.

mobile; the organ which is to be reached can then be readily treated according to the indications.

In Figures 1 to 8, for instance, it would be impossible to perform a cholecystectomy unless these bands have been first divided. This is especially true of Figure 5, in which the entire gallbladder was hidden from view. It is important that the fine blood vessels in these folds of peritoneum be ligated. It will also be noted that these bands are a continuation of the gastrophrenic omentum in many instances, as shown

the anatomy of the ducts and blood vessels, and their variations, assist us very materially.

Eliot² has reported twenty-three cases in which the common duct was encroached on, twenty-one of which followed a cholecystectomy. About forty-five operations have been performed for the reconstruction of the common duct.

REASONS FOR FAILURE

The reasons for these failures and many that have not been reported are: (1) variations in the ducts;

Fig. 12.—Gallbladder is pendulous, attached to the liver by a peritoneal band. Medial insertion of the cystic duct, which is rather long. The cystic artery is also long.

Fig. 13.—The caliber of the hepatic duct is small, the cystic is the same size, and inserts into the common duct close to duodenum. The hepatic artery is large; the cystic artery is very short.

Fig. 14.—The hepatic duct is between the portal vein and the hepatic artery. The hepatic artery is in close relation to the cystic duct, which is inserted close to the duodenum.

in Figures 1, 2, 4, 6 and 8, supporting rather strongly the advocates under Flint and his school that these bands are fundamentally developmental.

The foregoing has a direct bearing on the subject

(2) variations in the blood vessels, and (3) poor technique at operation.

1. *Variations of the Ducts.*—The cystic duct was inserted medially in 72 per cent. of the subjects exam-

Fig. 16.—All the structures under the liver. A very short cystic duct, medial insertion. The cystic artery under the hepatic duct. A very difficult case in which to perform a cholecystectomy.

Fig. 17.—Duodenal insertion of the cystic duct. Caliber of hepatic artery small; cystic artery the same size.

under discussion, because as soon as these bands illustrated by the drawings are severed, they separate into two layers, thereby disclosing the structures above the foramen of Winslow.

The reports from various sources of the failures following operations on the gallbladder and its ducts may be directly due to the ligation of the cystic duct and cystic artery within the covering of the peritoneum. It is more particularly in those cases in which the common duct has been encroached on that a study of

ined. This may be considered the so-called normal type (Figs. 9 and 10).

(a) A long cystic duct was medially inserted (Fig. 12). Improper ligation of the cystic duct may lead to the formation of a pseudo gallbladder.

(b) The very small caliber of the hepatic duct and the duodenal insertion of the cystic duct which runs parallel to the hepatic duct may be noted. The caliber

2. Eliot, E., Jr.: Surg., Gynec. & Obst., **26**: 81-102 (Apr. 1918).

of the hepatic duct is the same as that of the cystic duct, a very unusual type (Fig. 13).

(c) There was a very short cystic duct of large caliber and in close relation to the hepatic artery. The ducts and blood vessels were of large caliber (Fig. 15).

(d) Another source of considerable difficulty is the deep situation of all structures under the liver. All

an anastomosis was made between the pseudo gallbladder and the duodenum (Fig. 19). This type constitutes 24 per cent. of variations.

(f) Peculiarities in the shape of the ducts constitute another source of variation from normal. In Figure 22 the hepatic duct is S-shaped and in close relation to the cystic duct, which is rather twisted on itself.

Fig. 20.—Note the transverse branch coming from the hepatic artery and the close relation of cystic duct to this branch.

Fig. 21.—Transverse branch from the hepatic artery. Compare this with Figure 20.

Fig. 22.—S-shaped outline of the common duct and hepatic duct. Cystic duct is in close relation to the hepatic duct. The hepatic duct could easily be ligated while doing a cholecystectomy. It runs under the gallbladder; cystic artery in close relation to the hepatic duct. Cystic duct tortuous.

the structures are short; note how the right lobe of the liver hides the hepatic and cystic ducts (Fig. 16).

(e) There was an exceedingly long cystic duct measuring 3 or 4 inches in length, and inserted near the duodenum and revealing very little of the common duct. In these cases if the cystic duct is not traced to its insertion and ligated, a condition of pseudo gallbladder will result. Eisendrath³ and Floerchen report two cases, and the former mentions one other in which this occurred. I had one occur after a cholecystectomy

The hepatic duct here could easily be ligated.

(g) The cystic duct is inserted on the superior surface of the common duct. The cystic duct is twisted; the cystic artery runs over the cystic duct (Fig. 23).

(h) There is an unusual relation of the hepatic duct. It is above and covers the hepatic artery. The cystic duct is of large caliber and will naturally be longer on account of its insertion (Figs. 24 and 25).

Fig. 23.—The only instance of double hepatic artery coming from different trunks. Tortuous cystic duct inserted on the superior aspect of the common duct. Hepatic duct short. Cystic artery runs over the cystic duct.

Fig. 24.—Unusual relation of the hepatic and common ducts. The cystic duct is inserted close to the duodenum. Cystic duct large in caliber, unusually long. Two cystic arteries.

Fig. 25.—Cystic artery branched and anastomosis of the several branches. Portal vein below. Medial insertion of the cystic duct into the common duct, which lies between the hepatic artery and the portal vein.

in which the pseudo gallbladder was as large as the original gallbladder removed at a previous operation. While this particular pseudo gallbladder had distinct walls, there was no lining of mucous membrane. The inner wall was stained an indelible green. On account of continued jaundice and symptoms of Charcot fever,

(i) There is a very short hepatic duct, the cystic duct inserted into the common duct close to the liver (Fig. 27).

2. *Variations in the Blood Vessels.*—On account of variations that occur in the distribution of the vessels, the surgeon may often cut across an anomalous vessel or one whose course has been changed, and in his eagerness to stop hemorrhage may injure the common duct.

3. Eisendrath, D. N.: Recurrence After Operations on Biliary Passages. J. A. M. A. 69:1177 (Nov. 14) 1917.

- (a) The cystic artery runs above the hepatic duct in 51 per cent. of specimens examined (Figs. 9 and 10).
 (b) The cystic artery may run below the hepatic duct. This occurs in 27 per cent. (Figs. 13 and 15).
 (c) When the hepatic duct and portal vein lie on either side of the hepatic and common ducts, there is danger of injury to these structures (Fig. 14).
 (d) The cystic artery may be lateral instead of medial. This occurred in only one instance. The cystic artery was of unusual length (Fig. 18).
 (e) Transverse branches of the hepatic artery may occur above or below the hepatic duct (Figs. 20 and 21). When they occur below the hepatic duct the arteries may be injured, and in our desire to control hemorrhage the common or hepatic duct may be traumatized.
 (f) The hepatic artery may be double, coming from different branches. This was found in one specimen (Fig. 23).
 (g) The cystic artery may be branched, and these branches may anastomose with each other. This often

death finally resulting from inanition. We were unable to obtain a postmortem.

3. *Injuries to the Common Duct from Poor Technic.*—The points to observe are the proper placing of the sponges with retraction of the sponges by means of Deaver retractors, so that the gastrocolic and the gastrohepatic omenta can be made taut. Next in importance is the use of the left hand, which grasps the liver and gallbladder, bringing into plain view the structures around the foramen of Winslow. When these points are strictly adhered to, any operation on the gallbladder and its passages can be performed with comparative ease. When a cholecystectomy is performed, the right free border of the gastrohepatic omentum is incised and the cystic duct is isolated and ligated close to the common duct, while the cystic artery is ligated close to the gallbladder. This is a general rule that ought to be observed in performing all cholecystectomies if one wishes to avoid complications. A careful study of the drawings will show that if the artery is ligated close to the gallbladder and the

Fig. 27.—Very short hepatic duct, cystic artery double, one branch running under the cystic duct.

Fig. 29.—Remarkable size of hepatic artery; its tortuous course and its relation to the cystic duct, where it could easily be tied during a cholecystectomy.

Fig. 31.—Note the course, size, tortuosity and branches of the hepatic artery. A very unusual type. Cystic artery is inserted directly into the cystic duct. The hepatic artery covers almost completely the hepatic and common duct.

gives rise to considerable bleeding after the cystic artery has been considered ligated (Figs. 24, 25, 26, 27 and 28). This occurs in about 16 per cent.

(h) The hepatic artery may be tortuous and in close relation to the ducts. It may even cover the ducts, making all sorts of fantastic figures. When this occurs, the cystic duct is in close relation to it and the artery may be injured and even fatal hemorrhage may result (Figs. 29, 30 and 31). When operating on the common duct, it is important to locate it by means of a hypodermic syringe. It often happens that blood is drawn into the syringe instead of bile. It is easily understood how this can be done if one refers to the drawings, especially Figure 31. It is important not to tie the hepatic artery, as this is practically the sole supply of arterial blood to the liver. It is possible that some deaths may result from this accident:

Recently a boy, aged 10 years, was admitted to the Mount Sinai Hospital with the history that a wagon had run over his upper abdomen. He had signs of internal hemorrhage. After a careful search for the source of bleeding, the hepatic artery was found severed. The child was transfused with blood at the time of the operation. He lived two weeks following the operation, but there was a gradual loss of weight,

cystic duct is ligated close to the common duct there will be less necessity for secondary operations on the biliary passages.

Finally, when one considers that out of sixty-two specimens examined 33 per cent. of variations of the blood vessels and ducts were found, it behooves the surgeon to study the individual case more closely than he has done in the past.⁴

Child Welfare.—The distinct need for standardizing child-welfare laws is shown by the diversity among the states in child legislation. This variation in standards evidences a lack of clear thinking. A board of children's guardians is needed in every state. Minnesota has adopted a children's code which is a model for all other states in the methods used and the results obtained in legislation.—*School Life*, **2**:2 (May 16), 1919.

CRITICAL PERIODS IN DISEASE TREATED
BY BLOOD TRANSFUSION*

EDWARD E. LINDEMAN, M.D.†

NEW YORK

The blood is the highway for the carrying on of traffic on which animal life, from practically the lowest to the highest form, is dependent. It is a very complex tissue, many of the mysteries and intricacies of which are only now being revealed and reduced to the exactness of chemical science. Further research will unfold more, but there will ever remain that realm of darkness, unfathomable by intellect and research, but nevertheless existent.

For this reason, when the facts in the case cannot be reduced to chemical or biologic terms, a certain amount of empiricism in therapeutics must prevail. Empiric therapy will always offer ground for doubt, contention and debate about which reasonable, thinking men may differ. But even in the presence of empiric therapy an unbiased mind and keen clinical observer will obtain much that is of value from blood transfusion in many critical periods in disease.

In order to use effectively the instrumentalities available, it is essential to have a broad, comprehensive grasp of the subject. It may be worth while to call attention briefly to some of the substances in the blood aside from the formed elements with their oxygen-carrying powers and immunologic properties, namely: serum proteins; cholesterol; lecithin; fats; salts; sugars; fibrin ferments; amino acids; elements for synthesis into tissues; products of decomposition, oxidation and hydration; organ extracts; internal secretions; hormones; antibodies; bactericidal substances, etc.

It is apparent that the course of study in blood therapy should be directed, first, to an understanding of the normal blood, and then to a determination, as far as possible, of any excess or deficiency under pathologic conditions. It is not unreasonable to conclude that blood transplantation, in part or in toto, may favorably influence the course of many diseases other than hemorrhage and anemia, in which the indications are not so apparent, and that possibilities are opened for modifying the blood of a donor to meet specific needs in a given case.

REPORT OF CASES

CASE 1. A woman, aged 50, referred by Dr. W. A. Basteda, had a constant but moderate fever. There were no heart murmurs excepting those of low pitch and rumbling character, such as one frequently finds associated with impaired heart innervation. The systolic blood pressure was 102; the diastolic 66. The pulse was irregular and intermittent, varying from 90 to 116. There was multiple joint involvement associated with tenderness and swelling. This condition had existed for a period of five months, and seemed to simulate a form of rheumatic fever.

When I first saw the patient, he had a psychosis with frequent attacks of wild delirium and great pain. There was an exaggerated and coarse tremor of the muscles about the joints involved, with considerable rigidity. She was unable to take any nourishment. I agreed with Dr. Basteda in the opinion that she suffered from a toxic psychosis of infectious origin aggravated by rumen and was soon destined to reach

the point of exhaustion. It seemed to all of us associated with the patient that the case was a hopeless one.

The red blood count was 4,000,000 and the hemoglobin 80 per cent. Naturally, anything that would check the infection and reduce the toxicity would be indicated. All measures having failed, we resorted to blood transfusion.

She received in all four transfusions of blood of between 760 and 800 c.c. at two, three and five day intervals. After the first transfusion there was no apparent change excepting for its quieting influence. After the second transfusion the patient began to take nourishment, and her delirium was less. After the third transfusion, her delirium became increasingly less; she was able to take more nourishment, and her temperature began to fall, accompanied by a slower pulse rate, but one still intermittent. The pain, swelling of joints and tremors were markedly reduced. After the fourth transfusion, the heart sounds assumed a normal quality, the rumbling noises had disappeared, the pulse still remained occasionally intermittent, the psychosis and delirium subsided, her mind was clear, the pain and tremor of the joints were practically gone, and the temperature was normal. The patient was able to consume 2,500 calories a day. Her convalescence was uninterrupted. Some months later, however, she suffered a relapse, I understand, but to a very much milder degree.

I believe that repeated transfusions controlled the infection and reduced the toxicity. In support of this contention I have had a number of cases of infection in which transfusion quieted the patient, reduced the toxicity and overcame the bacteremia, with ultimate recovery of the patient. Whatever else may have occurred I will leave to your own analysis to supply.

I do not regard the fulminating, vicious types of infections, such as occur in the puerperium, or the acute variety in which death occurs within a few days, as favorable types for treatment, for these conditions become fatal before the treatment becomes operative.

The results obtained in malignant endocarditis with *Streptococcus viridans* bacteremia are not encouraging. One's efforts are almost invariably defeated by the lodgment of emboli in the brain, lungs, liver, kidneys, spleen, etc., which ultimately result in the death of the patient.

In long-standing cases of sepsis, even with bacteremia, the patient will frequently arrive at the point at which he has just enough protection to prevent further advance of the infection temporarily. The organism and the host then seem to exist side by side with indifference to each other until one or two conditions will prevail. The host will either overcome the organism, or the organism will advance further so as ultimately to overcome the host. During the stage of indifference, there may be very little or a moderate or a severe grade of anemia, malaise, debility, sapremia and poor nutrition, with absence or poor development of granulations about the infected area. This may be regarded as a critical period in the disease of the patient, and all measures should be directed toward increasing the patient's resistance. Blood transfusion will frequently offer an excellent field for application in these conditions. Infection is controlled, sapremia is reduced, and granulations are stimulated. The patients I have treated in cases that might be included in this group are too numerous to mention. For illustration it may suffice to mention nine cases of sepsis following mastoiditis with operation. In five, positive blood cultures of *Streptococcus hemolyticus* were obtained with five recoveries. In four, the blood cultures were negative in spite of the existence of a very severe sepsis elsewhere secondary to the mastoiditis. In three of these

* Read before the Section on Pharmacology and Therapeutics at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June 1, 1919.

† Dr. Lindeman is now a faculty member at Atlantic City, June 14, while lecturing.

cases the patients recovered. In the one case in which death occurred, a brain abscess existed, which it is believed was present long before the patient received any transfusions.

CASE 2.—In a boy, aged 11, who had double mastoiditis with involvement of the sinus and jugular thrombosis, the sinus was exposed and the clot removed from the jugular. This clot was found to extend also into the innominate vein, but could not be removed. There was a double septic pneumonia, a right septic pleurisy, osteomyelitis of the head of the left femur, and a positive blood culture of *Streptococcus hemolyticus*, with many colonies to each plate. After ten weeks of treatment this boy became well, excepting for the condition in the femur, which ultimately healed with joint fixation.

PERNICIOUS ANEMIA

The most typical feature in pernicious anemia to me is the variable and capricious course.

The clinical picture differs much according to the stage and specific seats of pathologic invasion. The variability is so great that doubt of accuracy of diagnosis is frequently felt. Most of the cases in my experience, however, of the atypical forms, have proved later to be pernicious anemia of Addison.

Because of the capricious course in this disease, one must be ever guarded in the presentation of any form of therapy, lest one attribute to it virtues which rightfully belong to the natural course of the disease itself. While one sees a favorable change occur in some cases spontaneously, only too frequently does death occur while the favorable moment for improvement is awaited. The number of cases of long course are relatively fewer. Hence, in the treatment of this disease, the skill of the physician and the patience of the family of the invalid may be taxed to the limit.

The story of this disease is too long even to touch on in the time allotted. Suffice it to say that when a patient has arrived at a critical period in pernicious anemia, there is no other therapeutic measure that has the power and efficacy of blood transfusion of unmodified blood in large amounts in robbing the disease of its terrors. Remissions may be provoked. When remissions cannot be provoked promptly, the patient bears the disease better and will be the better able to await the favorable moment for improvement with a prolongation of life.

TROPICAL SPRUE

Tropical sprue is a disease occurring principally in certain areas in the West Indies, Central and South America and northern parts of Africa, where it is found endemic.

There is present a stomatitis; a rough, furrowed and fissured tongue, which may later atrophy, and a severe gastro-intestinal disturbance and diarrhea, which may last from ten to twenty years. There is considerable emaciation and intolerance to iron, meat and other foods. The terminal stage is very frequently accompanied by a severe grade of anemia of the secondary type. Some of the anemias may approach a pernicious type.

CASE 3.—A typical case referred to me was in a man, aged 54, who had frequent attacks of stomatitis and a furrowed and an atrophic tongue. He had had a persistent diarrhea for twelve years, with from four to seven stools daily of the consistency of purée of peas. The patient had been treated by able clinicians, both in Cuba and in the United States. He was placed on a variety of rigid diets and treated by the

usual methods employed in this disease. In spite of this, his illness became increasingly worse.

I saw this patient for the first time in October, 1917. He presented a picture of pallor, extreme weakness and emaciation, with very poor appetite and an intolerance for almost any kind of food. The patient, an educated man, had a full realization of the nature of his disease, which was endemic in the country in which he resided. Having exhausted all measures then known for the relief of his ailment, he was unwilling to make further effort. His red blood count was 1,800,000; hemoglobin, 30 per cent.; white blood count, 7,000, and polymorphonuclears, 76 per cent. There was no macrocytosis, and there were no nucleated red cells. He was persuaded to try blood transfusion. He received three transfusions of 1,200 c.c. each, at weekly intervals. The diarrhea promptly ceased, his appetite improved at once, he was able to tolerate all varieties of food, he gained weight daily, and he has been well ever since.

Something more than the mere improvement in the anemia was responsible for the arrest in the disease. The diarrhea so characteristic of the disease exists long before the anemia develops.

I have had four other cases of this disease, with apparent recovery in every case.

CASE 4.—One case occurred in a man in whom the disease existed for a period of about eighteen months. The red blood count was 3,500,000; hemoglobin, 65 per cent.; white blood count, 8,000, and polymorphonuclears, 75 per cent. There was no macrocytosis and there were no nucleated red cells. He received two transfusions of 1,300 c.c. each at an interval of a week. All symptoms of the disease promptly disappeared, and he has remained well ever since.

It is therefore unlikely that the mere improvement of the anemia is responsible for the cure of the disease. Something else has been introduced by blood transfusion which is a corrective for the condition. All of these patients have returned to their homes and are useful citizens in the country in which they reside.

GAS POISONING

Gas poisoning may be regarded in a measure as an anemia, so far as the oxygen-carrying power of the blood is reduced.

CASE 5.—To show what can be done with this condition, it may be worth while to cite a case in a girl, aged 18, who, in January, 1915, was exposed to illuminating gas while asleep in her room, from midnight until 6 a. m. A gas pipe had exploded and the gas had escaped through a small hole in the floor of the room in which she slept. The window and the door of the room were closed. I saw this girl thirty-six hours after her exposure. She was then in deep coma, and there was a general rigidity, more on the right side than on the left, with no response to reflexes except the corneal reflex. One thousand four hundred c.c. of blood were removed, and 1,100 c.c. were transfused. The performance was repeated thirty-six hours later. She then began to show gradual signs of improvement. The rigidity grew less; she began to take nourishment when spoon-fed; reflexes returned and were exaggerated, with ankle and patella clonus. Consciousness, however, was not regained until the eleventh day after her exposure. After that her improvement was uninterrupted, and within two months she recovered completely, with no paralysis or mental disturbance. A severe acne vulgaris, which had existed for several years, cleared up after her transfusion.

I have had a similar experience with a case of tuberculosis, in which a severe acne vulgaris was present for twelve years. The acne cleared up miraculously after three transfusions; only the pitting and scarring of the skin from previous abscesses remained.

In five other cases of gas poisoning, all of the patients but one recovered.

NEPHRITIS

In nephritis, one may encounter a critical period in which blood transfusion may prove helpful. Following is a case in point:

CASE 6.—A woman, aged 32, suffered with subacute parenchymatous nephritis during the course of her pregnancy. The urine boiled almost solid with albumin. Many epithelial and white blood cells were found in the urine. The systolic blood pressure was 190; the diastolic, 120. The red blood count was 2,000,000; hemoglobin, 30 per cent. There was a marked pallor and a puffiness of the face, and edema of the extremities. She received 1,350 c.c. of blood. Within one week after the transfusion there was no evidence of a nephritis. Casts and albumin were absent, the edema subsided, and all symptoms disappeared. She has been well ever since. The blood pressure was not taken after the transfusion.

CASE 7.—I have had a similar result in the same type of nephritis in a patient, aged 45, without the existence of pregnancy. The red blood count was 3,200,000, and the hemoglobin 60 per cent. Recovery occurred promptly after the transfusion, with the disappearance of all symptoms and the absence of albumin in the urine. The woman has been well ever since.

These were cases of primary kidney disease in which the anemia was secondary. It is unlikely that the anemia was responsible for the nephritis. In many extreme grades of anemia there is frequently no impairment of the kidneys. In other cases there is a diminution in the functional activity, with only very slight traces of albumin in the urine. The functional activity, when impaired, improves with improvement in the blood condition.

CASE 8.—Another case that may be worth mentioning was of a man, aged 24, suffering with an acute nephritis, the cause of which was unknown. The systolic blood pressure was 190; the diastolic, 112. He had a retention of 210 mg. of nonprotein nitrogen per hundred c.c. The alkaline reserve was 22 per cent. Dichlorid and acidosis were present. There was a complete suppression of urine for four days. On the fourth day I removed 2,000 c.c. of blood. During the period of removal he was given 500 c.c. of sodium bicarbonate solution in order that he might not be overwhelmed by his acidosis. At the end of the bleeding his pressure fell very perceptibly, and transfusion was then begun. He received 1,200 c.c. of blood. I estimated that the patient was detoxicated 40 per cent. by the procedure. Sixteen hours after the transfusion he passed 500 c.c. of urine, which boiled solid with albumin. The clinical condition, however, was unchanged. He died several days later.

LEPROSY

CASE 9.—Blood transfusion was tried in a case of leprosy in a woman, aged 24, suffering with the disease for a period of ten years. During this time the disease was active, with areas of anehestia and thickening of nerve trunks, extreme nervousness, hysterical, poor appetite, lack of ambition, and a mental agony. The patient longed for death. She received in the course of a year six blood transfusions of 1,200 c.c. each. During the past six months the disease apparently has been arrested. Areas of anehestia are almost gone, the nervousness has subsided, and she no longer talks of death; in fact, she is showing considerable interest in life. Her physicians from Central America, who have recently seen her for the first time since she received her treatment, were greatly impressed with her remarkable improvement and the apparent arrest of her disease.

In another case under treatment at North Brother's Island, the patient has received two transfusions with considerable improvement in his condition. Reports of these cases will be published in full detail later.

ALUEKEMIC LEUKEMIA

CASE 10.—A critical period in a case of aleukemic leukemia occurred in a boy, aged 4. I saw this boy for the first time in February, 1916. He was then in urgent dyspnea, and was flailing about in bed restlessly. The skin was greenish yellow; the lips, blanched. There was a general glandular and marked liver enlargement. The child became unconscious during my examination. Time was not allowable for making blood tests or hemoglobin estimations. The smears showed a picture of aleukemic leukemia. Preparations for a blood transfusion were complete in fifteen minutes. By this time the child was in deep coma, and was rapidly approaching a state of exhaustion. Five hundred c.c. of blood were transfused through the external jugular vein from the mother. Five minutes after the transfusion there was a return of consciousness. Twenty minutes later, as I was about to leave the home, this child, who had just been within a few minutes of death from disease, sat up in bed and laughingly threw me a kiss good-by. He made a remarkable recovery. However, ten weeks later, the disease recurred, followed later by hemorrhage and death.

ANEMIA AND SEPSIS

CASE 11.—A case of anemia and sepsis occurred in a baby, aged 3 weeks, in October, 1916. The instrumental delivery of the child was very difficult, and the head was traumatized. A hematoma of the scalp, reaching the size of an orange, developed. The hematoma became infected and ruptured spontaneously. The temperature was 103, the pulse was too rapid to count. The red blood count was 2,000,000, and hemoglobin 26 per cent. One hundred and seventy-five c.c. of blood were transfused from the father through the external jugular vein. The vein offered a little difficulty for the insertion of the cannula, and by the time transfusion had started, breathing had ceased. The child was revived by the transfusion; the temperature promptly fell, and the infant has been well ever since, with normal development.

CASE 12.—A case of a different type occurred in a boy, aged 4, who had been operated on for the removal of the tonsils. There was considerable bleeding at the time of the operation. During the week following, though no more bleeding occurred, the child grew increasingly paler. He became very restless, occasionally vomiting, and was unable to take food. Skin petechiae were scattered over the trunk and extremities; there was no blood in the stools.

I received an urgent call in this case at 4 p. m., one week after the operation, and was on my way at 4:30 p. m. in a race against death, up hill and down dale and around mountain sides, for a distance of 60 miles. I arrived at 7 p. m., and found the little patient comatose, restless, and in urgent dyspnea, with extreme pallor. He was placed on the operating table immediately, and 500 c.c. of blood were transfused from the mother through the external jugular vein. Consciousness and color at once returned. The restlessness and dyspnea, however, had not diminished to a degree commensurate with the therapeutic procedure. If this child suffered from hemorrhage alone, the dyspnea and restlessness should have entirely disappeared. On further examination, the child's breath revealed the presence of acetone. Sodium bicarbonate was administered during the night, followed by a complete recovery the next day. The boy has been well ever since.

HEMORRHAGE

In cases of hemorrhage, blood transfusion is specific, no matter how extreme the hemorrhage, provided some life is still present. After an experience I am about to relate I am prepared to say that there is no condition so grave, from hemorrhage alone, that a patient cannot be revived by blood transfusion.

CASE 13. A man, aged 54, who used alcohol to moderate excess, was operated on, after several attacks of gastric pain and vomiting of blood, for gastric ulcer, in January, 1919. The ulcer was excised, and a gastro-enterostomy was performed. The course, for a period of ten days after the operation, was uneventful. Between the tenth and sixteenth days

after the operation, the patient had daily attacks of weakness, after which he vomited bright red blood. During this time his stools were dark and tarry. I saw this patient for the first time at 11 p. m. on the sixteenth day after his operation. He was very pale and weak; the pulse was 120, and the blood pressure very low. There was no increase in respiration and no dyspnea. I obtained a specimen of blood from the patient in order to make the necessary hemolytic tests. As I left his room he called me back to inform me of a sudden attack of weakness. Realizing the gravity of an attack of hemorrhage at this stage, I returned within two hours with a suitable donor. Everything was in readiness for a transfusion.

During my absence the patient became increasingly weaker, and on my arrival he was unconscious, with marked dyspnea and in shock. His respirations soon became paralytic in type, the head was thrown back. The respirations then became fewer and fewer until they were mere occasional gasps. The attending physician could feel no pulse. A tourniquet was placed on the patient's arm, but the veins did not distend. It was necessary then to make a small incision, exposing the medium basilic vein. Not a single capillary bled at the site of incision. There was no blood in the medium basilic vein; it presented itself, when exposed, as though it were a nerve trunk, and it looked like a piece of flat white tape.

By this time the patient stopped breathing, and no heart sounds were audible with the stethoscope. It requires but a few seconds to deliver blood by the syringe-cannula system, but even these few seconds were too precious to lose, and cold saline, which was the only thing at hand, was pumped into the vessels by my assistant until blood transfusion was started. Sixty c.c. of saline were introduced in the interim. After the patient received 200 c.c. of blood, he took an inspiratory gasp, followed by a paralytic expiration. When he had received 400 c.c., he was breathing more regularly; a flicker of pulse was perceptible. When he had received 600 c.c., there was a decided improvement in the pulse and an increasing depth of respiration. He opened his eyes and stared, but was not conscious. When he had received 800 c.c., he became startled, as though suddenly awakened out of a sound sleep, and wanted to know what all the fuss was about. The transfusion was stopped when the patient had received 1,200 c.c. The pulse and respiration were then quite satisfactory. He was then fully conscious, and breathing normally.

It may be worth while to note that when he became conscious he had no realization of his close proximity to death, and if he had reached the brink of the great unknown there was no spiritual or psychic evidence of it.

It is impossible to describe to any audience the extreme and dramatic clinical condition. I have never seen it before or since, and I expect never to see it again, namely, in the presence of all evidence of death from hemorrhage, revival was yet possible by blood transfusion. I believe the possibility for revival was a matter of a very few seconds, a second, or even a fraction of a second. I therefore contend that there is no condition so extreme from hemorrhage alone, if the heart still beats or is in a state of fibrillation, that revival is necessarily impossible with blood transfusion.

At the time the blood was obtained for hemolytic tests, there was a complete absence of fibrin in the specimen. The reason for the patient's bleeding then became quite obvious. The diminution or absence of fibrin occurs occasionally in cirrhosis of the liver. The liver in this patient was small. In all probability a degree of cirrhosis existed. I have learned by experience that when the fibrin content of the blood is diminished or absent, there is great liability to recurrence of hemorrhage, even after transfusion, and this emergency was therefore anticipated. Six days later the patient again had a severe hemorrhage, and bright red

blood was vomited. He was transfused at 4 p. m. At twelve o'clock that night he again had a hemorrhage, and at 2 a. m. he was transfused, after which an exploratory operation was performed. Bright red blood was found in the stomach, with a few small shreds of fibrin. The stomach and duodenum were thoroughly explored, and the intestine examined. No evidence of a bleeding point was obtained. The mucosa of the stomach generally was somewhat thickened and boggy, but otherwise normal. The patient was transfused immediately after the operation. He made an uneventful recovery and has been perfectly well ever since.

The statements herein contained are facts without exaggeration. They are used to call and direct attention to the use of blood transfusion in critical periods in many diseases, even when a severe form of anemia is absent. A great many more cases could be cited, but I trust enough has been said to stimulate an interest.

565 Park Avenue.

IODIN TINCTURES. WATER SOLUBLE *

TORALD SOLLMANN, M.D.
(CLEVELAND)

Proprietary preparations of iodine have been on the market for many years and advertised to physicians as superior to the official preparations—tincture of iodine and Lugol's solution (Liquor Iodi Comp., U. S. P.). The superiority claimed for these proprietary preparations is based on the allegation that the potassium iodide in the official preparations causes a local irritant action which is avoided in the proprietary preparations. The allegations seem improbable—certainly the local irritant action of potassium iodide must be regarded as negligible, as compared with that of hydroiodic acid contained in the proprietary preparations. Rather, it was surmised that any difference in local irritation following the use of the proprietary preparations was due to the fact that the iodine content in these preparations was insufficient to produce the irritation or, on the other hand, sufficient to have only a slight, if any, therapeutic effect.

The manufacturers do not seem to have published, and presumably do not possess, any comparative data on the degree of irritation produced by their preparations, as compared with the official tincture of iodine after this has been diluted so as to reduce its iodine content to that of the proprietary preparations. It was therefore decided to determine this point by applying various iodine preparations of an equal iodine content to the skin and also by extending the experiments in other directions. In these experiments two widely advertised proprietary preparations—Burnham's Soluble Iodine¹ and Sharpe and Dohme's Surgodine²—were included.

* From the Department of Pharmacology of the Western Reserve University School of Medicine.

¹ This investigation was supported by a grant from the Therapeutic Research Committee of the Council on Pharmacy and Chemistry of the American Medical Association.

² Examination in the A. M. A. Chemical Laboratory indicated Burnham's Soluble Iodine to be a solution of iodine in alcohol made miscible with water by the presence of some iodide and containing approximately 3 gm. of free iodine and 1 gm. of combined iodine in 100 c.c. (J. A. M. A. 50: 1055 [March 24, 1914]).

³ The A. M. A. Chemical Laboratory reported that Surgodine was an alcoholic liquid containing 2.51 gm. of free iodine and 1.72 gm. of combined iodine, probably present chiefly as hydrogen iodide, in 100 c.c. (J. A. M. A. 70: 257 [Jan. 26, 1918]).

Since these, however, are more or less secret in composition, I have devised a nonsecret preparation of the same character by the use of hydrogen iodid (hydriodic acid). The details of this preparation will be published in a pharmaceutical journal. Before use, each of these preparations was reduced by the addition of alcohol to a free iodine content of 2.2 per cent. (2.2 gm. in 100 c.c.).

COMPOSITION OF IODIN PREPARATIONS USED*

Nature of Preparation	Free Iodine	Percentage of Combined Iodine (including HI) as of HI.	Acidity as of HI.
Alcoholic solution	2.2	0.4	0.2
U. S. P. tincture (KI)	2.2	1.6	0.07
Alcohol with HI (author's formula)	2.2	0.7	0.6
Burnham's Soluble Iodine	2.2	2.7	1.4
Surgodine	2.2	1.2	0.8

*The numbers represent grams per hundred c.c. of preparation. Before use, each preparation was reduced with alcohol to a content of 2.2 per cent. of free iodine.

The accompanying table shows the composition of the solutions used, the total iodine being the same, the principal difference being in the acidity, which ranges from a minimum of 0.07 per cent. in the U. S. P. tincture (containing potassium iodid) to a maximum of 1.4 per cent. in Surgodine. The special preparation which I devised is intermediate and contains 0.6 per cent. The total combined iodine (including potassium iodid or hydrogen iodid) ranges from 0.4 per cent. in the alcoholic solution to 2.7 per cent. in the Burnham preparation.

EFFECTS ON THE SKIN

The solutions were painted on the skin of the inner surface of the forearm, each solution covering an area of from 15 to 20 mm. diameter; each application was allowed to dry before the next was added.

The results did not show any significant or constant differences. The actual results indicated that Burnham's preparation was the more irritant, and the U. S. P. tincture (reduced to the same iodine percentage) was the less irritant, but the differences were so small that they could easily be accidental.

In a preliminary test with three applications, no material difference could be detected between the different solutions.

In a second series, a measured quantity of solution was applied to two spots in three courses. The first course consisted of five applications at intervals of five minutes, and then a pause of thirty-five minutes. At the end of this time, the skin of all the areas was slightly tender. The second course consisted of five applications during sixteen minutes, and then a fifty-five minute interval. There was now considerable tenderness, alike for all the areas. The third course comprised five applications during fifteen minutes. Forty minutes after the last application, all the areas were equally sore. The depth of the stains ran in decreasing order from Burnham's (most) through Surgodine, hydrogen iodid, U. S. P. tincture, and alcoholic (least); but the differences were not great.

After removing the excess of iodine with alcohol, the reddening and edema at this time appeared as follows: Burnham's most, distinct papular edema and reddening; then the alcoholic; then the others, which were about alike.

On the following morning, the order of irritation was as follows: most, both Burnham's areas; next, one of the alcoholic areas; next, one of the hydrogen iodid areas; next, Surgodine; least, U. S. P.

PRECIPITATION OF ALBUMIN

Irritation is often due to precipitation of proteins, and this probably applies to the irritant action of iodine.

Therefore an investigation was made to determine whether there exist significant differences in this respect between the several iodine preparations.

Each of the diluted iodine preparations (2.2 per cent. iodine) was diluted with 10 volumes of water, to avoid precipitation of protein by the alcohol, and the diluted solution added to an equal volume of a 10 per cent. solution of natural egg-white in physiologic sodium chlorid solution.

The simple tincture, that with hydrogen iodid, Burnham's preparation, and Surgodine, produced an apparently identical coagulum. The U. S. P. tincture (diluted in the same way) produced only a turbidity; this also when the quantity of the iodine solution was doubled. Next morning, the albumin was coagulated as with the others. The reaction to litmus remained neutral.

The restraining action of the potassium iodid is limited, for the addition of an equal quantity of the potassium iodid tincture to the hydriodic acid tincture does not prevent immediate coagulation (1 volume potassium iodid tincture, 1 volume hydrogen iodid tincture, 10 volumes of water).

It is evident, therefore, that the potassium iodid of the official tincture has a restraining effect on the coagulation of protein. This would tend to make it less irritant than the other preparations. It is conceivable that this may be disadvantageous in skin protection, in which the fixative action is probably desirable. In this case, however, there is no object in using a water-miscible preparation, and the simple alcoholic solution of iodine would be fully as good as any of the others.

CAPILLARITY AND SPREADING

Dilute tinctures of iodine, when placed on the skin or on parchment, tend to distribute themselves so that the solution becomes most concentrated at the periphery (as in the accompanying illustration). In this manner, the periphery of an application on the skin may be blistered when the center is scarcely affected. If this property were more marked in one specimen than another, this would be equivalent to greater irritation. The illustration shows that this uneven distribution runs in the order: U. S. P. (potassium iodid tincture), most; Burnham's soluble iodine; hydrogen iodid tincture; Surgodine; alcoholic tincture (containing no potassium iodid), least.

The differences are in favor of the simple alcoholic tincture (which was formerly official) and adverse to the tincture containing potassium iodid (which is now official); but they do not impress me as of great importance, since they are even less marked on the skin.

I tried also to demonstrate differences in capillarity by the spreading or rise through filter paper; but the variations were insignificant.

CONCLUSIONS

The presence of potassium iodid in the official tincture of iodine does not seem to render this preparation more irritant. On the contrary, it is somewhat less irritant to the skin, and much less precipitant to proteins, than the simple alcoholic tincture, or the secret and nonsecret "miscible tinctures." The more even spreading and the more rapid coagulation of protein render the simple alcoholic solution of iodine probably the best for the "disinfection" of the skin; while the delayed protein precipitation by the U. S. P. tincture

would probably render this somewhat superior for the disinfection of open wounds. The secret and non-secret "water-soluble tinctures" do not appear to have any material advantages.

REACTIONS FOLLOWING THE ADMINISTRATION OF ARSPHENAMIN

REPORT OF REACTION IN A SERIES OF TWENTY-FIVE THOUSAND INJECTIONS*

WILLIAM H. GUY, M.D.
PITTSBURGH

So much publicity has been given some isolated instances of serious reactions following the intravenous administration of arspenamin that it seems worth while to tabulate the number and type of reactions seen in the course of a large number of injections of the drug, together with an attempt at classification of these reactions, more particularly with reference to their causes. At Camp Travis, Texas, we have given well over 25,000 injections of arspenamin and have attempted to keep a record of reactions as they occurred. In classifying and reporting this series it is pointed out that reactions following the administration of arspenamin are not so well understood that every case will automatically fall into any well defined group, either by virtue of certain classical symptoms or because of established etiology; nor can all reactions be avoided by the observation of certain fixed rules of technic; there are too many factors involved. Reactions necessarily have their origin in drug toxicity, technical errors, or in causes relative to the patient himself. Many reactions are undoubtedly due to drug toxicity, but there seems to be a deplorable tendency on the part of some to condemn the drug without sufficient consideration of other possible etiologic factors, particularly those relating to technic.

Just what constitutes a correct technic varies widely in the opinion of equally eminent authorities; but certain essentials have been established as the result of clinical observation and animal experimentation. Thus, most clinicians report fewer reactions when using dilute solutions, and we are informed that in animals¹ a dose of arspenamin which is well borne when given slowly for fifteen minutes will be surely fatal when injected in one minute in concentrated solution.²

Ehrlich,³ as early as 1911, pointed out the advantage of using dilute solutions. Just what dilution is best is an open question, varying, according to the opinions of different men, from 0.1 gm. to 3 or 4 c.c. up to 0.1 gm. to 50 c.c. of fluid; but most will agree that reactions are more frequent when using a concentration greater than 0.1 gm. to 15 c.c. Pollitzer⁴ states that 0.1 gm. to 20 c.c. will yield approximately a normal solution and should cause less disturbance in the blood stream. Salt solution as a diluent has been shown to be not necessary; but freshly distilled sterile water is considered essential, although there are those who believe that ordinary tap water will give just as good results. Wechselmann,⁵ in the early days of

arsphenamin, laid great stress on water impurities as a source of reactions. Certainly the source of any water not freshly distilled and sterilized will have some bearing on results. Danysz⁶ believes that reactions are due to a precipitation of arspenamin base in the blood stream owing to the carbonic acid present; various factors, such as the rate of injection, alkalinity and the salt solution, as well as the amount of acid in the blood, having a definite relation to the number and severity of reactions seen. He recommends small initial injections to vaccinate against reactions by increasing the amount of organic bases in the blood. Small preliminary injections may prevent some reactions; but at the same time we must consider the possibility of producing a resistant strain of spirochete, thus defeating the object of all therapy. Again, by such methods, much valuable time will be lost, particularly in dark field positive cases with negative Wassermann reactions. Herxheimer reactions can hardly be explained by Danysz's theory; such reactions have in my experience developed after small injections of the drug. Since oxidation products of arspenamin are quite toxic, it is wise to inspect each ampule for possible air leaks and to use the solution as soon after it is prepared as possible. Chemically pure sodium hydroxide is necessary as chemical impurities have been demonstrated to produce reactions. Incomplete neutralization of arspenamin has probably accounted for more avoidable reactions than any other one factor.

Schamberg, Kolmer and Raiziss⁷ state that acid solutions of arspenamin are from 50 to 60 per cent. more toxic than the alkaline. Again, one should observe carefully the rules laid down by manufacturers regarding the preparation of their particular brand of arspenamin; in dissolving the arsenobenzol brand, one may with safety use hot water; but with salvarsan (Metz) cold or at best lukewarm water should be used. To prevent undissolved particles from entering the circulation, the solution should always be filtered before it is used.

As to the selection of the brand of drug to be used, we recognize that different brands of arspenamin vary considerably in toxicity, and that different lots of the same brand vary to such an extent that methods of standardization are necessary before the drug is released for therapeutic use. The Public Health Service prescribes that manufacturers shall test each lot for arsenic content and toxicity. It is required that the arsenic content be not less than 29.5 per cent. nor more than 31.6 per cent. For the toxicity tests, five albino rats, non-pregnant, weighing from 100 to 150 gms., are injected with a 2 per cent. solution of the neutralized drug in doses of not less than 80 mg. per kilogram of body weight. It is required that 60 per cent. of the animals survive at least forty-eight hours. If more than one of the rats die, the tests are repeated and the total number counted in the result. Special rules regarding the care and feeding of animals are issued. Manufacturers' results are checked by the Hygienic Laboratory of the United States Public Health Service, thus assuring the profession a comparatively nontoxic product. In addition to these tests, manufacturers in this country supply a few ampules from each lot to some clinic, where a further check is made on the product for its human toxicity. Varia-

tions in toxicity are, however, still possible, and as a matter of fact are still encountered, presumably because one brand or some particular lot of the same brand of arspenamin may pass toxicity tests much higher than prescribed by the federal authorities. The two American manufacturers,⁷ whose products were used in this series state that their brand is being tolerated in much greater dosages than that prescribed in the official tests. Thus, one might expect that any brand of arspenamin would be comparatively safe; and yet there may be an excess number of minor reactions with one, because it just managed to pass the government toxicity requirements. Of these 25,000 injections, about 15,000 were of the arsenobenzol brand and about 10,000 were of the salvarsan brand. The arsenobenzol brand has made the better record of the two preparations. With the first lots of the salvarsan brand, reactions occurred twice as frequently as with the arsenobenzol brand. With the last few thousand injections, little difference in the two brands could be noted. It is noteworthy that the last 1,000 injections were given with only three reactions of any moment.

But with the best of technic and with a drug that is comparatively nontoxic, reactions will be encountered that have their origin in the patient himself. Reactions necessarily bear some relation to the relative functional integrity of the various organs; incompetent renal, hepatic, pulmonary, digestive, etc., functions account for many reactions that would otherwise be lacking. Also the temperament of the individual has some bearing on the frequency of reactions; what is a terrible ordeal to one individual is only an incident to another. Again, the status of the syphilitic infection itself has some something to do with the incidence of reactions. Goubeau⁸ attributes most febrile reactions to the disease itself, such reactions being noted most frequently in the florid secondary stage of the disease. Berman⁹ believes that most reactions are due either to acidity of the drug or an increased protein, especially globulin, in certain active syphilitic infections. Our own experience has been in support of such a theory. It seems reasonable that some reactions are due at least in part to the destruction of enormous numbers of spirochetes, liberating the protein of their bodies into the blood stream with the production of an anaphylactic type reaction. It has been our experience also that patients with elevated temperatures or with demonstrable pathology of almost any kind will not tolerate arspenamin well. We have seen a few cases with aggravation of syphilitic pathology due to the administration of arspenamin.

TECHNIC

Since so many reactions are properly ascribed to technic, a brief outline of the technic used in our work is in order before the report of reactions encountered is presented.

1. The usual preparation of the patient is ordered.
2. A general physical examination precedes the beginning of treatment, and a urinalysis is made before the injection of either arspenamin or mercury as a routine measure.
3. Instruments, glassware, etc., are sterilized by boiling.
4. Ampules are floated in alcohol to detect those not intact.
5. Ampules are opened and the drug dissolved in sterile distilled water, hot water being used only with the arsenobenzol brand.

6. The solution is neutralized with 15 per cent. sodium hydroxide to complete precipitation and clearing, after which a few drops in excess are added.

7. The solution is filtered and then diluted by running sterile distilled water through the filter until each 0.1 gm. of the drug is contained in 20 c.c. of fluid, the temperature of the solution being approximately that of the blood stream. Finally the solution is tested with litmus for alkalinity.

8. The solution is then placed in graduated glass cylinders hung about 3 feet above the level of the table, and supplied with tubing leading to a needle connection.

9. With the patient reclining, the bend of the elbow is cleansed with alcohol or painted with iodine, a small piece of gauze being placed just below the site selected for the injection. An assistant grasps the patient's arm just above the elbow, the patient closing his fist to distend the veins.

10. The check valve on the tubing is released, the operator pinching off the flow of the solution with the thumb and index finger of the left hand. The needle is held in the right hand, being introduced first through the skin and then into the vein.

11. On obtaining a flow of blood on the gauze, the assistant releases the arm, the patient opens his fist, and connection is made with the solution. Dosage is estimated at the rate of 0.1 gm. to each 30 pounds of body weight, and the requisite amount of the standard solution allowed to flow into the vein. The tubing is then disconnected from the needle, which is withdrawn after allowing a few drops of blood to wash it out, and a gauze compression is made over the site of the injection until all bleeding has stopped.

12. Following the injection, patients rest in the ward for an hour and a half, after which they are returned to their organizations, excepting those patients with infectious lesions who are kept in the hospital until all lesions have healed.

REACTIONS

We may include in the group of reactions due to technical errors those that developed in men that either disregarded instructions regarding preparation or were injected without preparation in special instances, as in early primary lesions in which the diagnosis had been made by the dark field method. Of the latter, eight of approximately 150 vomited within an hour after receiving a full therapeutic dose of the drug. Nothing further was noted except nausea preliminary to emptying the stomach, and later injections were without reaction, including twenty-five cases in which injections were given on each of three successive days after the method of Pollitzer.² The rest of our series of primary lesions (dark field positive), numbering 350 all told, were given the usual preparation the night before, and four of them were nauseated and emptied their stomachs. About eighty men in all stages of the infection who had had no preparation developed more or less severe reactions referable to the gastro-intestinal tract. From questioning patients at random I am convinced that at least every fourth one failed to carry out his instructions regarding preparation for one reason or another and still had no reaction. Cold solutions, I am sure, counted for three successive reactions with a moderate chill. On one occasion, the still being out of order, we used tap water, and five of forty men injected complained of shortness of breath, were flushed, and after a period varying from fifteen minutes to an hour, vomited and complained of intestinal cramps. Gonder's¹⁰ observation that small amounts of calcium and magnesium in water increased the frequency of reactions is of interest in connection with these cases when we find that there is a comparatively high content of these two elements in the water

supply at Camp Travis. Three cases of rather severe thrombophlebitis were seen that may have been due to the local implantation of infection, or more likely, I believe, the result of an infiltration of the drug between the coats of the vessel. The inflammatory process was an ascending one beginning at the site of injection and extending up the arm. These patients complained of pain and tenderness along the course of the swollen, inflamed and thrombosed vein, accompanied by an aggravated aching pain located rather vaguely at the shoulder. A moderate febrile reaction was noted, persisting over a period varying from ten to twenty days. Cold applications and splinting gave the most relief in these cases; all of the patients made uneventful recoveries, a hardened, sclerotic vein, however, persisting. On one occasion, when a new lot of salvarsan (Metz) was used, thirty-five severe reactions developed in thirty-five patients injected. Each had a severe chill from forty minutes to an hour after injection, the chill in some cases lasting as long as two hours. During reaction from the chill the patients vomited repeatedly, and a febrile reaction developed that in five cases persisted for three days. Nausea and vomiting persisted in one case for forty-eight hours. Intestinal cramps and diarrhea were present in twenty cases. Marked prostration lasting from twenty-four hours to a week followed in all cases. An albuminuria developed in thirty cases, in three of which numerous red blood cells and coarsely granular casts were also noted. All urines were clear ten days after treatment. No marked increase in blood pressure was noted. On the third and fourth day there appeared a herpetic eruption involving the lips, buccal mucosa, lobes of the ears, perianal region and penis in most of the cases. A polymorphonuclear leukocytosis was noted in every case, reaching its height during the second and third day and then gradually subsiding. The count was usually from 12,000 to 15,000, but in three cases it went as high as 50,000. These three cases showed two per cent. eosinophils and were the ones in which there occurred the most severe reactions. Slight fragility of red blood cells was noted in the more pronounced cases. All patients were entirely recovered and back on duty within two weeks, and have since taken arsphenamin without reaction. Later in the day we gave several tubes from another lot of the same product without reaction. This led us to believe that we were dealing with a particularly toxic lot of arsphenamin, and further administration of the lot was stopped.

On inquiry we found that the lot in question had passed the required toxicity tests at 80 mg. per kilogram of body weight, and that the lot had passed clinical tests before being released. We then decided to try out the lot further and gave 100 tubes without any save one or two very mild vasomotor type reactions, proving conclusively that the cause of these reactions lay in faulty technic rather than in the drug itself. The technic used was the standard technic as outlined, and the same that has been used before and since with the best of results. The sodium hydroxide (Merck) was freshly prepared, and the same solution was used subsequently without any trouble. The one source of trouble seems to have been in the water; that used was some of the first from a new still, and had stood in a new tank for about four hours before we used it. Just why this water gave such a serious lot of reactions I am not prepared to state, unless they

were due to bacterial or chemical contamination, the result of standing in the new metal tank. Emory¹¹ was able to demonstrate that reactions occurred more frequently when traces of lead and mercury were added to the water. Yakimoff¹² referred to the effects of water contamination by endotoxins of *Bacillus coli* and *B. pyocyaneus* in the same manner. Water from the same source has been subjected to chemical and bacteriologic tests with negative results, but this work was done after the tank had been drained and filled again so that the results obtained have been of value to us only in showing that the water supply is now what it should be. I have reported my notes on these cases in considerable detail because they illustrate how easily one may lay the blame for reactions unjustly on the brand of drug that he happens to be using. I am convinced that a good proportion of cases reported in the late literature as true toxic drug reactions were in reality due to errors in technic, or to causes relative to the patient himself.

It is difficult to place properly those reactions due to the drug itself. One must first eliminate every other source, and that is often quite difficult. We daily have patients speak of peculiar odors, tastes and sensations during administration of the drug. Such phenomena seem to be due to the drug itself. Innumerable instances of this kind have been noted and have rarely been followed by toxic manifestations of any kind. Two patients complained of severe pain radiating over the distribution of the dental nerves, one requiring an opiate. Vasomotor reactions with flushing of the face, dyspnea, cough and precordial pain we have seen in but 120 isolated instances, and in nearly all of these, with recourse to epinephrin and a few minutes' wait, we were able to finish the injection without further trouble. Schamberg, Kohner and Raiziss⁶ believe that these early reactions are due to traces of an unknown impurity which they call substance X. We were not able to demonstrate consistently any excess of reactions of this type with any particular lot of the drug. In one case a generalized subcutaneous edema with lowered blood pressure persisted thirty-six hours in spite of epinephrin. A generalized urticarial eruption developed in two cases. A mild generalized dermatitis developed after eight weekly injections, persisted for three weeks, and then the patient made an uneventful recovery. A generalized pruritus developed an hour after the administration of a single therapeutic dose, and persisted for ten hours. A chill, followed by a fever and usually vomiting and diarrhea, was noted in twenty isolated instances.

Of particular interest to me has been a group of about forty cases in which reactions developed that could be shown to be due to an aggravation of a non-syphilitic pathologic condition. For instance, several men who had a few bronchial rales at the preliminary examination developed a moderate chill, cough, and generally a rather severe aggravation of mild bronchitis. One of the patients, recently an influenza victim, developed bronchopneumonia in the same manner. Patients with yellow sclera developed a marked icterus in only three of many similar cases. There were two with an aggravation of previously noted urinary findings following the cautious exhibition of the drug. Most patients with evident mild chronic

¹¹ Emory, E.: Bull. Soc. franç. de dermat. et de syph., **24**: 37, 1913.

¹² Yakimoff, quoted in Abhandlung über Salvarsan, **13**: 1-12.

interstitial nephritis tolerated the drug well. Contrary to what we expected, no unfavorable results were noted in five proved cases of pulmonary tuberculosis. In another case of the same kind, arsphenamin could not be given, because with each injection there would be an exacerbation of pulmonary symptoms. Generally we noted that men with elevated temperatures, except those due to the syphilitic infection itself, did not tolerate the drug well. Fischer,¹³ in 1915, in an analysis of published deaths from arsphenamin, stated the belief that most of the deaths were due to some unsuspected disease, and that all the evidence at hand exonerated the drug of most of the mishaps credited to it. While we find it difficult to dismiss the subject so easily, still it seems reasonable to believe that some of the reactions attributed to drug idiosyncrasy have in reality been due to some unsuspected pathologic condition.

We have had two cases with early reactions in which we were forced to the conclusion that a drug idiosyncrasy existed. In one case an alarming train of symptoms developed after each injection of the drug. About three hours after receiving arsphenamin this patient developed a chill, vomited, and was quite prostrated. His heart action became weak and irregular. His symptoms persisted from forty-eight to seventy-two hours, even with comparatively small doses of the drug. Epinephrin did not seem to be of any use. Finally, a mild dermatitis appeared on the forearms, and further injections were temporarily discontinued. After a period of about four months, following the suggestion of Stokes,¹⁴ a preliminary hypodermic injection of $\frac{1}{50}$ grain of atropin sulphate was given and 0.3 gm. of arsphenamin injected without any reaction whatever. Unfortunately this man was released, and further data on the case are not available. In the case of the other patient, with practically identical symptoms, but milder, we were able to administer arsphenamin, by giving 0.1 gm. as a preliminary injection, and following that with the rest of the injection in an hour. We have found it to be advantageous to inject the drug very slowly in these cases. The method of preliminary small injections suggested itself in connection with Danysz's² recommendation that all first injections of the drug be small ones to vaccinate against future reactions. Of delayed reactions we have seen six examples. These patients had no trouble until the third or fourth day after injection, when they developed a train of symptoms differing but little from those seen earlier. The onset was more gradual, as was convalescence, and prostration seemed greater than with the usual type of reaction. These reactions usually occurred after the patient had had two or more injections of the drug. We have noted a second reaction of the same type in two patients. This, coupled with the fact that delayed reactions are comparatively infrequent, has led me to believe that such reactions occur as the result of individual peculiarity, or an unsuspected pathologic condition.

Of Herxheimer reactions we have seen only a few. One man with mucous patches developed a severe glossitis following the injection of 0.4 gm. of the drug. Two showed marked aggravation of throat ulceration following the 0.3 gm. preliminary dose recommended by the War Department. In another case, mucous patches became confluent, and with extension of the

larynx produced a complete aphonia which persisted for several weeks. It is my opinion that Herxheimer reactions are the result of the stimulating activity of nonsterilizing doses of arsphenamin, and that they may be avoided by full therapeutic dosage.

There have been two fatalities that may be ascribed in any way to antisyphilitic treatment in this series. Approximately 3,000 patients have been treated, some for a short time on account of transfer of station, and others over considerable periods. In one case, after two 0.4 gm. injections four days apart, the patient developed an acute dilatation of the stomach, death occurring on the ninth day. Necropsy revealed nothing of interest except that arsenic could not be found in any of the viscera. This patient had taken arsphenamin before without reaction according to his statement, and so, since this was only one of a group of 165 injected the same day, we feel that this case must represent one of an unsuspected underlying pathologic condition or one of drug idiosyncrasy. The other case was that of a soldier much overweight, but otherwise as far as we were able to determine, quite normal. He received 0.6 gm. of arsphenamin, and after a seven day interval another of the same size. He also received two injections of 1 grain each of mercuric salicylate. According to routine, the urine was examined before each injection of arsphenamin, and found normal. On the third day following his last injection of arsphenamin, he reported to his regimental surgeon for mercury. At that time he stated that he felt quite well except for some local tenderness in the buttock following the previous injection of mercury. The urine was not examined. He was given 1 grain of mercury, and the next morning was found unconscious in bed. A catheterized specimen of urine which revealed almost a solid coagulum of albumin, was loaded with blood and granular casts. He died the same day and at necropsy we found an acute diffuse hemorrhagic nephritis. Thus we may again point out the necessity of routine examination of urine before each injection of either arsphenamin or mercury.

Owing to the fact that most of our patients are handled on the ambulatory plan, reporting from organizations by appointment, receiving their treatment, waiting an hour and a half, and then returning to their commands, necessarily there have been some reactions that we have not seen; but since regimental surgeons were instructed to send all such patients to the hospital as soon as they were seen, we feel that any that did so occur were of minor importance.

While my classification of these cases may not meet the approval of all, and many of my opinions and statements are open to just criticism, yet I feel that the total picture presented is worthy of consideration in that it tends to strengthen the growing conviction that arsphenamin as marketed today is a comparatively safe product.

Since this article was written, the toxicity requirements for arsphenamin have been raised to 100 gm. per kilogram of body weight.

500 Pittsburgh Life Bldg.

ABSTRACT OF DISCUSSION

DR. WILLIAM ALLEN PUSLY, Chicago: I want to express my great appreciation of the very admirable character of Dr. Guy's paper. It seems to me that it is the sort of paper that does a great deal of good. There is only one thing in which I would criticize it, and that is his tendency

¹³ Fischer, R.; Deutsch, mod. Wchnschr. 11:965 (Aug. 14) 1915; abstr. J. A. M. A. 65:1147 (Sept. 25) 1915.

¹⁴ Stokes, J. H.: Atropin and Induced Autoinflammation, J. A. M. A. 72:254 (Jan. 25) 1919.

to give a clean bill of health to the drug when anything happens to the patient. It is surprising when you have good arsphenamin how carelessly you can use it and have no trouble. When you remember how it is being given all over the country with any sort of technic it is a remarkable tribute to arsphenamin. And yet, when a man like Dr. Guy who uses a technic which is beyond criticism, has some trouble, the suggestion immediately is that there was something wrong with the lime content of the water. You can give arsphenamin in an acid solution and in some cases the patient will have no reaction, literally no reaction, and yet they come and tell us that if any accident happens, it is because we have not used a chemically pure hydroxid solution or the patient has got a little lead from the glass or something of that sort. You have given him 4 or 5 grains of arsenic and yet they tell us he has died from an infinitesimal dose of lead.

DR. HAROLD N. COLE, Cleveland: I would like to report two cases of dermatitis exfoliativa following the use of arsphenamin. In one case, the dermatitis developed after the last injection of a series of six given about two weeks apart. The other patient who had had six injections of the arsenobenzol brand of arsphenamin developed the exfoliative dermatitis about three days after the last injection. In both

materials is at hand. I have attempted to be fair in all of my statements, and while I would not have you think that arsphenamin is fool proof, yet I do believe that this report amply supports my opinion that arsphenamin as marketed today is a comparatively safe product.

ARTERIOVENOUS ANEURYSM

REPAIR BY FREE VESSEL TRANSPLANTATION *

STERLING BUNNELL, M.D.

SAN FRANCISCO

The report which follows is one of an operation for arteriovenous aneurysm of the femoral artery at the junction with the profunda artery. In the operation, a free transplantation of vein was made.

REPORT OF CASE

History.—A private in the San Francisco base hospital in France four weeks previously had been shot by a machine gun bullet, which entered the right thigh, passed through the

Fig. 1.—Condition of aneurysm as found. Profunda artery and vein enter sic posteriorly.

Fig. 2.—Condition of vessels confronting for repair. Through the opening in the femoral artery can be seen the mouth of the profunda artery. The cut ends of the internal saphenous, profunda, and femoral veins can be seen.

Fig. 3.—Completion of vessel suture, showing graft of internal saphenous vein with two valves into gap in femoral vein. Femoral vein narrowed by suture for end to end suture with graft; lateral suture of femoral artery, and ligation of profunda vein.

cases there was a high temperature, reaching to 104 F., and in the case of the male the temperature has persisted after all evidence of dermatitis has gone. In the female it had been present for about two weeks when I last saw her. There were no symptoms from the kidneys in either case, except a slight degree of albuminuria.

DR. HENRY MICHELSON, Minneapolis: I wish to supplement Dr. Cole's case. We had a patient in Dr. Sweitzer's service who developed an exfoliative dermatitis three days after the third treatment with the arsenobenzol brand of arsphenamin. We made a blood culture and found *Streptococcus viridans* and, therefore, thought that, instead of the injection, was the cause of the dermatitis.

DR. FRED WISE, New York: I am sorry that I cannot give any definite figures, but after administering the arsphenamin in the Vanderbilt clinic in thousands of cases we have not seen one case of dermatitis resulting from its use.

DR. WILLIAM H. GUY, Pittsburgh: Dr. Pusey's remarks are certainly quite apropos, but he is not quite just in his criticism. When one meets with thirty-five reactions in thirty-five patients injected, and later uses 100 tubes of the same lot without reaction, proof positive of faulty technic or

femoral artery and vein, then through the right pubic bone, through the bladder, and on out through the left buttock. For a few weeks the urine escaped through the left buttock, and then the fistula closed.

Examination. There was a red, expansile pulsating swelling 4 by 2½ inches, with considerable ecchymosis extending widely over the thigh. Pain was complained of. There was a strong thrill over the swelling, which was transmitted for several inches up the vein. A very loud and characteristic bruit could be heard, not only over the tumor, but also over the iliac vein, the abdominal vena cava, and even in the back over the thoracic part of the vena cava. It sounded like the puffing of a locomotive, and its distribution showed that the aneurysm was arteriovenous in type. There was, in the leg, no distention of the surface veins with transmission of the bruit and venous pulse, distally, as it was later found that there were two valves in the upper end of the internal saphenous vein, as shown in the graft in Figure 3. The color

*Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL by omission of a review of the subject with comments. The complete article appears in the reprint, a copy of which may be obtained on application to the editor.

and warmth of the leg, when it was at rest, were normal; but there was no pulsation in the dorsalis pedis or posterior tibial arteries.

Prognosis.—From the large size of the aneurysm, a spontaneous cure could not be hoped for. The prognosis in such a case is bad. Though the disappearance of arteriovenous bruits in the external iliac and femoral veins has been reported, a spontaneous cure of arteriovenous aneurysm is rare, and not to be expected. A simple arterial aneurysm is much more likely to undergo spontaneous cure than is an arteriovenous one.

The dangers were: increase of size; pressure symptoms, such as occlusion of the vein and collateral vessels, with resulting gangrene; embolism; sudden and fatal hemorrhage, and inflammatory changes.

In an arteriovenous aneurysm, these complications, though always impending, are a little less likely to occur than in arterial aneurysms, because of the opening into the vein. The proximal vein furnishes an open exit for the arterial stream and also acts as a safety valve, protecting the sac to some extent from the poundings of the pulse wave.

In cases of arteriovenous aneurysms, nutritional changes eventually set in, and the circulation of the limb is not able to increase sufficiently when called on for work. There is a tendency to cyanosis, coldness, lymphedema and pain in the limb.

It is more dangerous to ligate the femoral artery above the profunda than below it. A ligation of the femoral artery below the profunda will usually, in a young man, not result in gangrene. If the femoral artery and the profunda are both ligated, gangrene of the leg is practically certain. It was necessary, therefore, in operating in the present case, to plan some plastic work on the vessel rather than ligations.

Operation. The external iliac artery and vein were first exposed and occluded by the use of paper clips. These were found to be entirely adequate for vessels of this size and gave a gentle pressure that did not injure the vessels. The femoral artery and vein below the tumor were also exposed and occluded by clips. The intermediate vessels, including the aneurysm, were then dissected out. Scar tissue of the bulkt tract enveloped the aneurysm. There was a general firmness swelling, an inch in diameter, of the femoral artery and vein. A sac-like projection from the antero-external surface of the artery, and an opening 1 cm. in diameter joined the artery and vein (Fig. 1). In the course of the dissection several holes soon developed in the front wall of the aneurysm, which was of poor consistency; and it was necessary to keep a thumb on these holes to prevent copious hemorrhage. The vessel had been clamped above and below, but the blood would gush from the profunda artery and vein that came up directly beneath the aneurysm. As the thumb, which was preventing the hemorrhage, was held directly over the profunda vessel, the dissection and the clamping off of these vessels was impossible. This furnished a predicament which

was difficult. Pressure on the abdominal aorta would stop the flow from the profunda artery, but not that from the profunda vein. It was necessary to excise the aneurysmal part of the femoral vein and to tie each of the six venous tributaries that came into the aneurysm.

In the femoral artery, the opening into the sacculc and that into the vein were trimmed with scissors into one opening. The mouth of the profunda artery, as it emerged from the posterior part of the femoral artery, could be seen directly beneath the hole that was trimmed out in the femoral artery. Figure 2 shows the condition of the vessels at this stage. With No. 16 Kirby needles and No. 0-9 black silk, a lateral suture of the artery was made. This left only a slight constriction of the lumen of the artery, so that at this point the diameter was a little over half the normal. Suture, rather than ligation, is indicated, even if but one-third the lumen is retained. In this case, a transverse suture line was impossible, as the vessels could not be stretched longitudinally. On releasing the clamps on the artery (the distal one first), the blood stream was reestablished.

The provision for a venous return for the leg next confronted us. In this case,

Fig. 4.—Method of end to end vessel suture, using wire crotch to hold guide sutures and serve in the place of an assistant.

the profundus and internal saphenous veins were cut, and there was a gap of 1½ inches in the femoral vein, so that if ligated, gangrene would be the probable result. When a main artery is ligated, it has been found best to ligate also the accompanying vein. This gives a balanced circulation and less chance of gangrene. Conversely, when the artery alone is patent, it is necessary to reestablish also a venous return. Joseph Blake gives as an indication for amputation, in the case of a fractured femur, the occlusion of both femoral and internal saphenous veins.

A segment of 2 inches of the internal saphenous vein was excised and transplanted as a free graft between the ends of the femoral vein. The length was made ample to avoid

tension. Vessel ends, when cut, retract. I have read of stretching them out and by so doing overcoming gaps, but I have never found this to be possible. Nor does it seem commendable to overcome gaps in vessels by flexion of joints. As the caliber of the transplant was much less than that of the femoral vein, and especially as the femoral vein had been considerably dilated by the arterial pressure, it was necessary first to reduce the caliber of the ends of the femoral vein by suturing half way across the lumen of each. Then, end to end unions, with the graft, were made (Fig. 3).

I believe it desirable to deviate, in suturing vessels, from the orthodox method, as laid down by Carrel, in not smearing the tissues with petrolatum. Petrolatum is objectionable in that it provokes the formation of serum in wounds, tends to prevent tissue surfaces from healing together and encourages infection. Instead of using petrolatum as a preventive measure against the clotting of blood, I use a 1 per cent. solution of sodium citrate, washing the vessels and keeping the field wet with it. I am confident of the merit of this deviation in technique, as with it I had uniform success in making free transplantations of vessel segments in dogs.

A mechanical aid, which greatly facilitates the delicate work of suturing vessels, is the small wire crotch, as shown in Figure 4. The guide sutures are held closely and steadily by it, so that the sewing is made easy. The hands of the assistant are not in the way, and the part to be sutured is free from the influence of their tremor. The crotch is held stationary and in a vertical position by the heavy clamp, which rests on the field, and the guide sutures are transferred from one crotch to the other as the suturing progresses. There is thus presented in turn, for suture, each of the three sides of the triangle. I prefer my original form of crotch,¹ though various adaptations of the principle have been published since my description of it.

Postoperative Result.—At the completion of the operation, the leg was somewhat cyanotic from the long time that the vessels were clamped. A pulse could be felt in the femoral artery distal to the part repaired.

In an hour the cyanosis cleared, and from then on the temperature, color and appearance of the two legs were equal. The thrill and bruit were gone, and did not reappear. The pulse could not, at first, be felt in the dorsalis pedis. This was evidently because the pulse wave was interrupted by the narrowing of the caliber of the artery at the suture line, as in a week the artery, having had time to dilate at its narrowed caliber, the pulse in the dorsalis pedis made its appearance and remained present. There were no subjective symptoms. In three weeks the patient was allowed to get up and go about, and his leg gave him no trouble. In a letter from him written May 5, 1919, five months later, he stated that since his operation he had had no circulatory trouble in his leg; that he had a complete absence of such symptoms in the leg as cramps, coldness, weakness, heavy feeling or pain, and that he was able to feel the pulse in the dorsalis pedis and posterior tibial arteries as well as in his normal foot. As an additional test of the circulation of the leg, an open wound, which he had through the dorsum of his foot, healed soon after the operation.

BOTULISM FROM CANNED ASPARAGUS*

CHARLES THOM

RUTH B. EDMONDSON

AND

L. T. GILTNER

WASHINGTON, D. C.

Sickness and even death from the ingestion of spoiled food are repeatedly mentioned in the literature. Much of the information offered however is vague. The identification of the actual type of decomposition responsible for these cases has been usually incomplete. Such reports leave hope neither for relief from the suffering of the individual nor of proper safeguards against further poisoning. Recently the work of Dickson¹ followed closely by the report of Nevins² led to the identification of *Bacillus botulinus* as one cause

of poisoning cases occurring in America. Botulism has been regarded as rare, apparently because the cases that occurred went unrecognized. The discussion in the literature, although presumably adequate, failed to identify the poisoning cases which actually occurred. A considerable series of such cases in man and domestic animals have been described by Dickson,¹ Dickson and Burke,³ Burke,⁴ Buckley and Shippen,⁵ Shippen,⁶ Graham, Brueckner and Pontius,⁷ and Graham and Brueckner.⁸ The toxicity occurrence and conditions of growth of *B. botulinus* are thus becoming better defined.

The study of actual material involved in such cases may be expected to furnish means for the detection and elimination of danger from such foodstuffs. In January, 1919, four persons died in Boise, Idaho, as a result of eating asparagus that was taken from the jars and served cold in a salad. A portion of this salad, three jars of asparagus canned in the same pack as that used in the salad, and the cap of one of the two jars whose contents were incorporated in the salad were secured by W. T. McCall, state club leader of Idaho, and forwarded for investigation to his chief, O. H. Benson, States Relations Service, Department of Agriculture, Washington, D. C. These were given to the Microbiologic Laboratory of the Bureau of Chemistry for study. Clinical reports of three of these cases follow:

REPORT OF CASES

CASES 1 and 2 (Report of Dr. S. M. Forney).—About noon of Jan. 8, 1919, I was called to see two colored people, a man and a woman. From the woman I learned: That morning both she and her husband awoke feeling normal. A few hours later he began to feel a choking sensation in his throat; his voice became husky and he had a feeling of weakness (paralysis) beginning in the feet and creeping upward. At the time I called (2 p. m.) he was unable to talk; but he could understand and answer by shaking his head. He had no pain; breathing was labored, pulse rapid. The wife was beginning with the same symptoms, but these were not as yet so marked. She complained of a choking sensation and swelling in her throat but was able to tell what they had eaten the night before, nothing since, etc. They were ordered to the hospital. Before the ambulance arrived the husband died and the wife died on the road to the hospital, apparently choked to death. There were seven negroes at the meal. Five ate asparagus, four of whom died within thirty-six hours. The fifth escaped though he ate heavily of asparagus. I saw only the husband and wife mentioned, but the others died as these did.

I afterward learned that the asparagus, which we suspected at the time, was home-canned, cold-pack method with single sterilization, and that at the time it was opened one woman remarked that it smelled spoiled. The host answered: "It can't be. I canned it myself."

CASE 3 (Report of Dr. H. M. Holmerson).—In the case of C. H., she with a party ate of canned asparagus at 4:30 p. m., Jan. 7, 1919. It was noticed at the time of eating that the asparagus did not taste just right. No symptoms were noted until 9 o'clock of the following morning, when she first

noted a sensation as though the tongue were swollen. She was not at all alarmed until 12 o'clock, when she heard that two others of the party were severely sick; then I was called.

At the first call at 12 o'clock I found considerable paralysis of the glossopharyngeal nerve. The articulation was distinct, although it was an effort for her to talk. There was no disturbance of the vision except that objects appeared to move to the left side. She could walk but veered to the left for the reason, as given by her, that the objects for which she started seemed to move over to the left and she followed the objects. There was no pain. She had a settled conviction that she would not live. There was no distress of mind about her own condition. Her only worry seemed to be that her husband, who was present at the dinner party, might be taken sick on his car, he being a Pullman porter. I immediately placed her on drop doses of gelsemium. For about an hour there seemed to be some improvement.

At 3:30 p. m. the paralysis had progressed to such an extent that there was drooping of the eyelids and a feeling of slight numbness with tension of the right arm. All the muscles were involved, showing complete involvement of the right brachial plexus. Speech was much more labored, articulation distinctly thickened. Swallowing had become difficult, the gait had become distinctly swaying in character. The mind was clear; there was no distress mentally or physically.

At 5 o'clock the hypoglossal nerve had become affected; swallowing of liquids or solids was impossible. There was a continual flexing of the right hand and beating of the arm on the arm of the rocker in which she was sitting to relieve the feeling of deadness, as she described it, in the arm. The speech was very much thickened and required great effort, although she could deliver a full sentence at a time.

At 8 p. m. there was complete paralysis of the tongue. The paralysis of the muscles of the throat and face had progressed to such an extent that she could only whisper a word at a time. At this time there seemed to be a beginning of paralysis of the pneumogastric nerve. Breathing began to be labored, heart action was slow, being at this time about 50. The eyes could only be partly opened and that only by an effort of throwing back the head.

At 10 o'clock she ceased all efforts at speaking; the respirations were slow and labored, twelve per minute. The pulse was 40. From this point all respirations became slower with a sort of gasping sigh until 1:30 a. m., when death took place (Jan. 9, 1919).

There was no pain at any time, and the paralysis of the muscles of respiration did not give any distress in breathing, although it was labored. The patient's mind was clear at all times until she lapsed into unconsciousness, about 10 o'clock.

PREPARATION AND CONDITION OF THE ASPARAGUS

The following information as to the preparation of the asparagus was obtained from the daughter of the dead woman who had canned it. This daughter was not present at the fatal meal. The asparagus was washed thoroughly, cut into lengths, and allowed to stand overnight before processing. Most of the jars examined by Mr. McCall and others showed evidence of poor sealing; some were actively leaking. All of the lids had been previously used and the rubbers were of an unsatisfactory grade.

Examination of the three jars of asparagus and the cap submitted to this laboratory showed the contents of two of the jars slightly turbid, with the asparagus tips partially broken but without changes definitely attributable to spoilage. The cap of the third jar was badly swollen, showing that there had been considerable pressure, but there was no spurting of the liquid on opening. The contents were dark-green, much disintegrated and had a most offensive odor like that of butyric acid, which should have warned the consumer that the material was spoiled. Dried material which had leaked about the seal made the odor evi-

dent before the lid was removed. This odor would be commonly regarded as putrefactive. The small sample of salad had this odor along with others of decomposition. The separate cap from one of the jars whose contents made part of the salad gave this odor to a very offensive degree.

Even the casual examiner of this material could not have failed to detect its spoiled condition. The information obtained shows that one of the persons who made the salad remarked on its peculiar taste. Yet the asparagus was used and eaten, contrary to the opinion of Weinzirl⁹ that food which is offensive or putrid is automatically discarded as unfit for human consumption.

The danger of even tasting a suspected foodstuff is clearly pointed out by Dickson's report¹⁰ of the death of a woman after tasting 2 teaspoonfuls of canned corn as taken from the jar.

ORGANISMS ISOLATED

Microscopic examination of the salad, asparagus juice and washings from the extra cap in sterile water revealed among other organisms a large terminal-spored bacillus measuring from 0.6 to 0.9 micron by 2 to 6 microns resembling *Bacillus botulinus*. This organism has proved to be a strain of *B. botulinus*, and will be designated for convenience the "Boise strain." It was isolated from the foregoing materials in pure culture by inoculating small quantities (1 loop to 1 c.c.) of heated (80 C. for ten minutes) and unheated material into sheep's brain medium made as described by Burke.¹ Growth with the characteristic butyric acid odor was obtained after twenty-four hours' incubation at from 24 to 26 C. under anaerobic conditions. Shake cultures were then made in a series of deep glucose agar tubes, dilutions being made with a platinum loop. After colonies developing gas appeared, the tubes were filed about an inch below selected colonies, the agar cylinder was pushed free from the broken edge, the surface seared with a platinum needle, and the colonies were fished and transferred to sheep's brain broth and a special glucose beef infusion¹¹ broth, reaction 0.5 alkaline to phenolphthalein. There was some difficulty in adjusting the reaction exactly to 0.5 alkaline, owing to changes in the sugar during sterilization. After sterilization it was often found to be as highly acid as 1.5. To overcome this, sterile alkali was added aseptically after sterilization in the autoclave.

The bacilli as cultivated in the brain medium are large, from 0.5 to 0.6 micron by 2 to 6 microns, the average length being 3 microns. They have slightly rounded ends and occur singly or in pairs end to end. In glucose beef infusion there is a tendency to form short chains. Terminal spores are formed readily (within forty-eight hours) in the brain medium, but are delayed in the glucose beef infusion to about the third week. Good sporulation takes place in plain milk, but is somewhat delayed. The spores are wider than the vegetative cell, thus bulging it slightly, giving the characteristic club shape to the bacilli. Free spores are somewhat oval and measure from 0.9 to 1 micron by 1 to 1.3 microns.

¹¹ Van Lennigem, E.: Der Bacillus botulinus und der Botulismus, Kofle, W., and von Wassermann, A.: Handbuch der pathogenen Mikroorganismen, Jena, Ed. 2, 4: 509, 1912.

The bacilli are actively motile, having from four to eight peritrichic flagella¹² which were easily stained by the use of van Ermengem's¹³ method. This stain also revealed the presence of a capsule, a fact not mentioned in the literature. The bacilli stain readily and evenly by the usual stains and are gram-positive. The organism is a strict anaerobe, but will grow in mixed culture with aerobic organisms, such as the white *Sarcina* (van Ermengem¹¹) with yeast (Shippen⁶) and in our own experiments with *B. coli*.

Surface colonies on glucose agar in an atmosphere of hydrogen are small, being from 3 to 5 mm. in diameter, round to amoeboid with nucleated center, whitish, slightly raised and glistening. Under low power the center is less finely granular than the remainder of the colony. Deep colonies are round to lenticular. The plates are often overspread with a fine cloudlike growth with an arborescent edge. Colonies develop slowly in from six to seven days at 25 C.; but at 37 C. there is good formation within three days. The organism grows best and produces its toxin at 37 C. contrary to the findings of van Ermengem with respect to his strain, but in harmony with other workers in this laboratory with cultures of the Nevim strain.

CHARACTERISTICS OF THE ORGANISM

The cultural characteristics in ordinary differential mediums are as follows: In plain and wort-agar-shake cultures there is very slight growth, but there is vigorous growth with gas formation in glucose agar; slight turbidity, afterward clearing up in plain standard broth and wort broth, with gas formation in the latter; glucose, lactose and sucrose broth are fermented, but with gas formation only in glucose; no reduction of nitrates; production of indol in tryptophan broth; no visible growth on potato; and gelatin is readily liquefied. The reactions in plain and litmus milk are interesting in view of those obtained by van Ermengem. He reports no change in milk. In our experiments there was a fine coagulum, peptonization beginning at about the fifth day and being completed at the thirteenth. Litmus milk showed a slight reddening, afterward decolorization and peptonization. There was no visible growth in either Uchinsky's or Raulin's solutions. The bacilli were grown in a 1 per cent. sugar yeast water medium for fermentation tests. The sugars were tested for acidity by adding a few drops of sterile litmus solution to each tube. There was slight acidity, but no gas in xylose, galactose, mannite, maltose, inulin, trehalose, rhamnose and glycerin. There was no gas and no acidity in dulcitol.

The bacilli grow best in a medium that is slightly alkaline (0.5 alkaline has been the reaction of the mediums in our experiments), although it did grow and produce toxin in brain medium with a reaction of -2 to phenolphthalein and in plain glucose broth with an acidity of 2.0. Shippen⁶ reported growth and toxin production in a sugar-free medium with an acidity of 3, and according to Dickson¹ a reaction of + 3.2 does not entirely inhibit production. The sheep's brain broth and a cooked meat medium¹⁴ used in our experiment have usually been covered with a layer of neutral oil. However, the oil is not necessary, as good growth

and toxin production was obtained without it by deep inoculation into the mass of finely divided animal tissue. Ordinary development also takes place in the closed arm of a fermentation tube without the oil stratum.

More than 200 laboratory animals have been used in testing the toxicity of this strain. Unfiltered and filtered broth cultures were fed (put directly into the throat by syringe) or injected subcutaneously, intravenously or intraperitoneally into guinea-pigs, rabbits, white mice and rats. The majority of animals used, however, were guinea-pigs. In most of the experiments the minimum lethal dose of the toxin used for a 350 to 400 gm. guinea-pig was 0.001 c.c. of a filtered glucose beef infusion culture incubated six days at 37 C. The minimum lethal dose was determined by intraperitoneal injections of the guinea-pigs. The virulence of the toxin produced varies somewhat with the same medium. One culture incubated at room temperature (26 to 28 C.) for one month produced a toxin whose minimum lethal dose was 0.005 c.c. Another culture incubated at room temperature (35 C.) for twenty-eight days produced a toxin with a minimum lethal dose of 0.0001 c.c. This was the most powerful toxin obtained.

The experimental animals were watched carefully for symptoms, and postmortem examinations were made. Control animals were also carefully watched. The onset of the symptoms of poisoning began as early as from six to eight hours after injection in cases in which the dosage was excessive. With minute doses, symptoms appeared much later, in some cases from eighteen to twenty-four hours after injection and even as late as thirty-six hours afterward. They were briefly as follows: a general weakness followed by partial paralysis of either or both posterior and anterior extremities, dilatation of the pupils, dyspnea, laryngopharyngeal paralysis with loss of voice, inability to swallow, ptalism and nervousness. Before death ensues, the animal lies flat on the abdomen with the head resting on the floor of the cage and all four extremities outstretched.

Necropsies disclosed few definite lesions. There was a general hyperemia of the internal organs as well as of the brain and meninges. In some cases hemorrhages have been noted in the lungs and in the abdominal cavity. In two cattle there were cardiac and intestinal hemorrhages. The formation of gas takes place after death very quickly in the stomachs of the animals. In several instances the stomach was ruptured.

Histologic sections by one of us (Giltner) from the lungs, liver, kidneys, spleen, brain and meninges showed evidence of thrombi in the blood vessels suggestive of Dickson's findings. In some of the vessels there were accumulations of leukocytes with an occasional fully formed hyaline thrombus. There was usually degeneration of the parenchymatous tissue in the liver and kidneys.

DETECTION AND ELIMINATION OF DANGER FROM FOODSTUFFS

From the experimental data accumulated in this study the following examples were chosen as having a more or less direct bearing on the detection and elimination of danger from foodstuffs:

The thermal death point of the organism was tested. Cultures of the Boise strain in the brain medium and

glucose beef infusion showing an abundance of free spores were heated without pressure for varying periods of time at temperatures varying from 80 to 100 C. The organism survived heating to 100 C. for one hour, but failed to grow in subcultures from tubes heated for two hours. In a series of tubes under pressure, growth occurred in fifty per cent. of the tubes autoclaved at 10 pounds pressure for fifteen minutes, but no growth has been observed after using 15 pounds pressure for fifteen minutes. While there was no growth after thirty-six days in those tubes submitted to 15 pounds pressure for fifteen minutes, apparently proving the death of all spores, they are still under observation. Mrs. Barker reports the retarded germination of spores heated at high temperature. She found that spores in the brain medium survived at 15 pounds pressure for ten minutes, the growth in subcultures being determined only after the fifty-third day. Our results show that the organism is sufficiently resistant to account for its survival in canned food.

A relative idea of the stability of the toxin produced by the Boise strain was determined by the application of heat as well as light. The filtrate of glucose beef infusion cultures (a diatomaceous filter of standard type was used to separate the bacterial cells from the culture medium) was heated in the water-bath to the following temperatures and held for the lengths of time described in Table 1 and guinea-pigs were injected to determine the virulence.

TABLE 1.—EFFECT OF HEAT ON TOXIN

Temp. C.	Time of Holding, Minutes	Dose (Minimum Lethal Dose 0.001 cc.)	Occurrence of Death in Animals
62	30	1.0	Within 22 hours.
64	45	0.75	Within 21 hours.
65	30	1.0	Within 8 days.
66.5	30	0.5	Within 11 hours.
68	30	0.45	Within 11 days.
70	0	0.4	Within 5 days.
70	30	0.75	1 of 4 guinea-pigs died within four days; other survived.
73	0	1.6	Within 25 hours.
73	10	1.6	Survived.
75	0	1.0	Survived.
75	5	1.0	Survived.
75	10	1.0	Survived.
80	0	1.0	Survived.
80	5	1.0	Survived.
Control untreated		1.0	Death in 18 hours.

From these results it is apparent that the toxin was attenuated somewhat by subjection to 68 C. for thirty minutes, as the guinea-pig lived over a period of eleven days. The toxin is destroyed at some point between 70 and 73 C. by heating for ten minutes. When the temperature reached 75 C., no appreciable period of heating was required to destroy it.

Cotton-plugged tubes of toxin were exposed to direct sunlight on a fire escape and to diffuse light in front of a window with a southern exposure for the time described in Table 2. Guinea-pigs were then injected to determine the virulence.

It is evident from these results that the toxin is highly resistant to the action of light since exposure to diffuse light for two months and to direct sunlight for two, three, four and twenty-four hours respectively, failed to diminish its virulence. Exposure to the direct rays of the sun for forty hours, however, destroyed the toxin.

In order to gain an idea of the concentration limits of sugar and salt on the growth and toxin production

of this strain, a series of tubes of cooked meat medium with varying percentages of glucose and sodium chlorid, respectively, were inoculated and incubated at 37 C. for one week. Those cultures showing growth in the highest percentage were injected into guinea-pigs to determine toxicity. There was growth and toxin pro-

TABLE 2.—EFFECT OF DIRECT AND INDIRECT LIGHT ON TOXIN

Kind of Light	Time	Dose (Minimum Lethal Dose 0.001 cc.)	Results
Diffuse	1 month	1	Death in about 28.29 hrs.
	2 months	1	Death in about 42 hours.
Direct sunlight	2 hours	1	Death in about 16 hours.
	3 hours	1	Death in about 16 hours.
	4 hours	1	Death in about 16 hours.
	24 hours	1	Death in about 36 hours.
	40 hours	1	Survived.
Control, same toxin, kept in sealed bottle in ice box.		1	Death in about 16 hours.

duction (guinea-pigs died within twenty hours) in 35 per cent. glucose but not in 45 per cent. and in 5 per cent. sodium chlorid but not in 8 per cent. Control guinea-pigs fed the 35 per cent. glucose and 5 per cent. sodium chlorid solutions, respectively, showed no symptoms. These results, though preliminary, indicate the alarmingly wide range of growth for this strain of *B. botulinus*.

FOOD SPOILAGE UNDER ICE BOX CONDITIONS

Canned corn, peas, deviled ham, and tongue, canned Swiss cheese and sausage were inoculated in the center of the mass with the Boise strain and placed on a tray covered only with cheesecloth in an ice box at an average temperature of 12 C. Controls were kept at the same temperature. These foods were observed daily for physical signs of spoilage. After twenty-four hours the cheese smelled "off," but the odor was not typical of botulinus. After four days the peas had a peculiar odor, but, as in the case of the cheese, it was not typical of *B. botulinus*. After a week, both the control and inoculated foods showed mold. Small portions of these foods were taken from the extreme edge of the can and emulsified in physiologic sodium chlorid solution, heated at 80 C. for fifteen minutes and then transferred to glucose beef infusion to determine growth. The organism was recovered only from the Swiss cheese and the peas, the two foods that showed some signs of putrefaction.

This preliminary experiment shows that the organism can live and multiply in as low a temperature as 12 C., therefore foods set away in the ice box are not free from danger if *B. botulinus* happens to be present.

EFFECT OF THE SPORES OF THE BOISE STRAIN IN THE ANIMAL BODY

Cultures in glucose beef infusion showing free spores were freed from their toxin by heating at 80 C. for ten minutes. Animals inoculated or fed these cultures showed no symptoms. In another experiment the cells were freed from their toxin by washing in physiologic sodium chlorid solution. They were centrifuged twenty minutes at high speed seven different times. The supernatant liquid was pipetted off, fresh sodium chlorid solution was added and the cells were thoroughly separated after each centrifuging. The cells were allowed to stand twice in sodium chlorid

solution for one hour intervals and after the last centrifuging were placed in the ice box over night. Two guinea-pigs and a rabbit when injected with these washed organisms died within seventy-two and ninety-six hours, respectively. Part of these same cells were then rewashed seven times (making fourteen in all) and inoculated immediately into guinea-pigs. These animals survived.

In another experiment cultures were washed seven times as before. Animals fed these washed organisms died within twenty-four hours. From these results it is apparent that cells may be successfully freed from their toxin by heating at 80 C. and by washing, but that washing the cells free is a very difficult matter.

The organism was recovered several times from the feces of the animals fed spores either freed from toxin by heat or by washing, and from the liver and spleen of animals injected with cultures. Colonization of the bacilli in the body has not been proved thus far, but the foregoing isolations from feces prove that the organism goes through the guinea pig's body in twenty-four to forty-eight hours with undiminished virulence.

A few preliminary experiments on the agglutination and complement fixation reactions of the Boise and Nevin strains have been made, but thus far the results have been unsatisfactory. At this time a sheep and a horse are being immunized against the toxin of the Boise strain, for future experiments.

In testing the toxicity of this strain for larger animals, two dogs, four adult cattle, one hog and four chickens were used. Dog 355, weighing about 5 kg., was injected subcutaneously with 5 c.c. of toxin (minimum lethal dose 0.001 c.c.) and Dog 363, weighing about 20 kg., was fed 13 c.c. of the same toxin. The injected dog showed typical symptoms within forty-eight hours and died within four days. The fed dog survived. A month afterward the same dog (363) was given more toxin by mouth, the dose being 20 c.c. (minimum lethal dose 0.0001 c.c.). The dog survived, indicating a strong resistance to toxin taken by mouth.

Of the four cattle, two were injected and two were fed with toxin. Cow 422 was injected subcutaneously with 10 c.c. of toxin (minimum lethal dose 0.005 c.c.); Cow 344 was given 35 c.c. by mouth, and Cow 431, 40 c.c. by mouth of the same toxin. After nine days the cattle had showed no effects from the toxin. Cow 422 was then injected subcutaneously with 20 c.c. more of toxin (minimum lethal dose 0.0001 c.c.); Cow 344 and Cow 426 (no previous treatment had been given No. 426) received 20 c.c. of toxin subcutaneously. All of these cows succumbed, showing typical symptoms and postmortem findings. Cow 422 died in fifty-two hours, Cow 344 in seventy-three hours and Cow 426 in seventy-four hours. The only cow that survived was Cow 431, which was fed the toxin and received no injection.

A six months old hog (3245) was fed 30 c.c. of toxin (minimum lethal dose 0.005 c.c.). No symptoms were observed. Three weeks later the same animal was injected with 5 c.c. of toxin (minimum lethal dose 0.0001 c.c.) subcutaneously. Three days later the only symptom noted was a very slight incoordination of the hind parts; the animal otherwise appeared normal. One week after the treatment the hog succumbed with botulism. These results with the dogs, cattle and hog seem to indicate that they are

resistant to the toxin when it is taken by mouth, but are not resistant when it is injected.

The four chickens were fed with varying amounts of toxin (minimum lethal dose 0.0001 c.c.). The first received 4 c.c., the second 1 c.c., the third 0.5 c.c., and the fourth 0.1 c.c. Those receiving 4 and 1 c.c. of toxin, respectively, died, the first in eighteen hours, the second in forty-six hours. The other two survived, showing no symptoms. These results indicate that the Boise strain when fed in large amounts is toxic for chickens.

COMMENT

Considered in its relation to poisoning from canned food, the results of this study are in the main consistent with the findings of Dickson¹ and Dickson and Burke,³ but differ in marked respects from those of van Ermengem¹¹ and others who studied the organisms isolated from sausage in Europe. The Boise strain differs also from the Nevin organism as studied by Nevin,² Buckley and Shippen,⁵ by DeBord of this laboratory, and from the findings of Graham and his co-workers¹⁵ in the experiment stations of Kentucky and Illinois. The van Ermengem and Nevin organisms are easily killed, even in the spore form, by boiling. Such bacteria cannot be a factor in the spoilage of canned goods processed by any of the well-known methods. The Boise organisms, however, and certain of the organisms of Dickson may clearly be expected to survive occasionally in canned food processed by any of these methods. The discordant results obtained in our autoclave experiments have not been fully analyzed. The rate of penetration of heat into different mediums, the effects of varying hydrogen-ion concentration and the protective effect assumed to be due to some substances must all be considered in a complete analysis of the results. These factors are already being studied in at least two laboratories,¹⁶ but the fact remains that the Boise organism, like the organism of Dickson and Burke, will at least occasionally survive any method of processing in which heavy steam pressure is not used.

Successful canning, so far as the danger from such strains as the Boise organism is involved, depends not so much on the method of work selected as on the rejection of infected material at the start. Dirty, wilted and partly rotted food carries multitudes more of organisms into the canning process than fresh, sound, clean fruits and vegetables. Dirty tables, dirty jars and lids, sewage-polluted water and flies are sources of contamination which should be eliminated. The material should be processed according to the best experience available. Finally, it must be frankly recognized that an occasional jar, or series of jars, may yet spoil because some factor escaped all these precautions. Such food should be destroyed, not salvaged, not fixed up into salads, mince meat or pie stock for human food. The toxin present may be destroyed by heating until jar, lid and rubber, as well as contents have actually reached the boiling point.

Typical spoiled cans are readily identified. Doubtful cases, however, occur frequently. A consumer unfamiliar with a particular product is frequently puzzled by its odor as it comes apparently sound from a can in good condition. Cooking, as recommended

15. Compare references 7, 8 and 12.

16. Thompson, G. E.: Temperature-Time Relations in Canned Food During Sterilization, *J. Indust. & Engin. Chem.* **11**: 657, 1919.

by Dickson, appears to be the practical method of destroying possible toxin in such material; even this, however, leaves the spores viable. Feeding suspected food to domestic animals, without safeguards, is clearly undesirable. Chickens, pigs and cattle survive when fed the Nevin organism in moderate amounts. Dickson's chickens, however, and some of those used in our experiments, died. The work of Buckley and Shippen¹⁷ and the Kentucky¹⁸ results show that the excreta of these animals are clearly a menace to other species, since horses died when fed the hen dung from experimental coops. In our experiments the organism was recovered from hen dung forty-eight hours after feeding, and was toxic for guinea-pigs. The organism has also been recovered in full toxin-producing power from the feces of guinea-pigs fed cultures freed from toxin by heating to 80 C. for ten minutes. Such recovery was possible within twenty-four to forty-eight hours after feeding, but has not succeeded after longer periods. Fecal contamination from such sources is, therefore, possible.

B. botulinus is not the only heat-resistant anaerobe responsible for putrefactive spoilage. In the examination of many samples of spoiled canned food it has been necessary to depend on the animal experiments to identify those which were toxic. The examination of several lots of material has shown organisms closely resembling the Boise strain in morphology, heat resistance and physical evidences of spoilage, but without toxic effect when fed. In such a case of known history, for example, the spoilage of the jars of food was traced to the well water on the premises. Experimental packs in the well water exhibited typical spoilage in spite of scrupulous care in canning. A survey of the premises proved the contamination to be due to sewage from the household. In spite of its offensive odor, the experimental animals were not harmed by this material. Many such products are doubtless eaten without toxic effect.

Viable spores of an anaerobe find ideal conditions for development in a properly packed and processed can. Such a can presents conditions in which an obligate aerobe cannot develop. Hunter and Thom¹⁸ found 224 out of 530 cans of salmon to contain living spores of a particular organism without evidence that this species had caused changes in the material after it was canned. In this particular work no strict anaerobes were isolated. Mrs. Obst¹⁹ of this laboratory, however, found that anaerobic spore formers were abundant in the sardine canneries, and that, in spite of commercial precautions in processing, it was only necessary to incubate a few cans at 37 C. to obtain one or more "swells."

Careful examination of cultures of experimental packs, together with the known observations of persons connected with the Boise cases and the Newark cases,²⁰ clearly agree that canned food infected with either strain of this series is definitely spoiled food. It usually shows gas, marked disorganization, and an odor that is offensive and would be classed by most

people as putrid. No careful observer can open typical cans without detecting their condition. Dickson in studying material infected by *B. botulinus* has recorded the same observations, but has established no correlation between the physical examination of canned goods and the safety of the consumer. On the contrary, he has issued a general warning against all home-canned food.

Our observations are in harmony with the conclusions of Rosenau,²¹ who says: "All the cans examined by Professor Weinzirl and Dr. Cheyney have been eaten by the scientific workers at the experimental lunch club, and careful note of any effects has been made. Not the slightest symptoms have been produced. These favorable results were clearly predicated, for the kinds of bacteria and molds in merchantable goods are of the harmless sort." From this quotation it is clear that the Harvard investigators have selected canned food sound from physical examination and found it safe. It is equally clear that they did not consume food from cans that showed physical signs of spoilage. The application of their conclusions is strictly limited by the assumption put forward by one of them (Weinzirl¹⁹) that obviously spoiled or putrescent food will not be eaten. This premise has proved unsound in the two cases we have cited, because the food was offensive; it was eaten, and the consumers died. Unfortunately, there are many people who do undertake to salvage canned food which they know to be spoiled or in some stage of decomposition. The warning, therefore, is clearly not to avoid canned food, but to avoid spoiled food canned or uncanned, but especially if canned.

SUMMARY

1. The Boise poisoning case was due to canned asparagus spoiled by a strain of *B. botulinus* (Boise strain) whose spores survive 10 pounds pressure for fifteen minutes or 100 C. for one hour.

2. This strain has an optimum growth temperature of 37 C., high heat resistance, and hence approximates the characteristics given by Dickson for his No. III, but differs markedly from the organism of van Ermenegem and the Nevin organism as studied by Shippen.

3. The toxin produced by the Boise organism is destroyed by heating to 75 C., or by heating for ten minutes at 73 C. The toxin varies in strength with changes in cultural condition. At the highest toxicity obtained, the minimum lethal dose for a guinea-pig weighing from 350 to 400 gm. was 0.0001 c.c. of a filtered glucose beef infusion culture inoculated twenty-eight days at 35 C. and injected intraperitoneally.

4. Bacilli freed from toxin by washing or spores freed from toxin by heat do not produce symptoms of poisoning when fed or injected, but have been recovered in virulent form from feces of fed animals.

5. All cultures of the Boise organism have a characteristic and offensive odor which was clearly evident in the canned material connected with this case. This has been referred to as butyric but, certainly, in many foodstuffs would be inseparable from the putrefactive group of odors.

6. Decomposition occurring in a can or jar properly packed, exhausted and sealed is necessarily anaerobic. When physical evidence of such decomposition is present, the material should be destroyed, not eaten.

Clinical Notes, Suggestions, and New Instruments

THE WALCHER POSTURE VERSUS THE CESAREAN SECTION

H. F. BIGGAR, M.D., CLEVELAND

Is it not surprising how many cesarean sections are being performed by the younger class of obstetric surgeons? An obstetric surgeon reports that, though he has not been in practice more than ten years, he has already passed his one hundred and fiftieth cesarean section. It may be questioned whether the conditions warrant the operation. Has not nature perfected the proper way for normal birth?

Cesarean section is justifiable only when the following conditions are present; contracted, deformed or diseased pelvis; placenta praevia; eclampsia; fibroid tumor; kyphosis; osteosarcoma of the pelvis; hypertrophic elongated cervix; uterine fibroma; malignant disease of the cervix uteri; face presentation with chin directly posterior; funnel pelvis; inoperable carcinoma of the uterus; presentation of the head, cord and foot; atresia of the vagina; deformities of fetus of abnormal development, including the hydrocephalic fetus; ruptured uterus; hydramnios; suppurating ovarian cyst; double uterus; adherent placenta and ruptured uterus; Bright's disease; difficult labor after ventral fixation of the uterus; scar of old operations for other conditions; vaginal occlusion; dyspnea; cyanosis; anasarca and albuminuria; dermoid cyst of the pelvis; malignant ovarian tumor; labor with impaction; rigid os; pendulous abdomen; malignant disease of the rectum, and anteversion of the gravid uterus.

Why not try the Walcher posture before using the knife? I have found this posture sufficient in quite a number of patients, even though cesarean section was advised by reputable surgeons, and the patients were willing to submit to the operation.

THE WALCHER POSTURE

The patient is placed in the decubitus position on a table with one end so elevated that the nates project well over the edge, the legs hanging perpendicularly, the feet not touching the floor. When the head presents in the soft parts the end of the table is lowered so that the top is level. The patient is then put in the extreme lithotomy position and delivered with or without instruments. This position increases the diameter of the superior strait of the pelvis one-quarter inch or more.

TYPHOID FEVER TRANSMITTED THROUGH THE BREAST MILK OF THE MOTHER

REPORT OF A CASE IN AN INFANT OF EIGHT MONTHS*

HENRY HEIMAN, M.D., NEW YORK

March 19, 1919, there was admitted to the adult medical service, at Mount Sinai Hospital, a nursing mother suffering from typhoid fever. Two days later the patient's baby was brought to the pediatric service, afflicted with the same malady. A bacteriologic study of the mother's breast milk disclosed the presence of typhoid bacilli.

HISTORY OF THE MOTHER'S CASE

The patient was a married woman, aged 29, whose family history and past history were quite negative except for an attack of influenza six weeks previously. Two weeks before admission to the hospital she suffered an onset of pain in the lower back region, headache, fever and chills. There was no epistaxis. Diarrhea had been present for several days. The patient was found acutely ill, restless and actively delirious. The lower pole of the spleen was felt 3 inches below the costal margin. Definite rose spots were present. The pulse was dicrotic. The temperature while the patient was in the ward showed a typhoid curve, gradually falling in the fifth week of the disease from 105 F. to normal. The

blood showed a leukopenia, the white count being 4,200 with 68 per cent. polymorphonuclears and 32 per cent. lymphocytes. The blood culture showed the presence of typhoid bacilli, and the Widal reaction was positive. A culture of the breast milk revealed the presence of actively motile bacilli corresponding in every respect to the typhoid organism.

HISTORY OF THE INFANT'S CASE

The patient was an infant, aged 8 months, whose birth history was perfectly normal. It had been breast fed until two weeks before admission to the hospital, having been weaned because of the mother's illness. There had been no previous illness or physical defect. Four weeks before the admission to the hospital there had been an onset with a rise in temperature to 101 F., but the infant seemed as well as usual. In ten days it had apparently recovered entirely. Then there followed a sudden rise of temperature to 105. Both ear drums were incised, but the fever continued. There was no vomiting or diarrhea. There were no convulsions. The baby appeared acutely ill, with rapid respirations, and flushed cheeks. There were no rose spots. The spleen was enlarged, the lower pole being felt 1 inch below the costal margin. The rest of the physical findings were negative. The blood count was 8,000 white cells, with 74 per cent. polymorphonuclears and 26 per cent. lymphocytes. The blood culture showed the presence of typhoid bacilli, and the Widal reaction was positive.

COMMENT

We have found the experience worthy of report because of its very unusual occurrence. We have been unable to find any similar record in the literature. In one case however, reported by Lawrence,¹ typhoid bacilli were found in the breast milk in a nursing mother of 23, ill with the disease. But in this instance the infant escaped infection.

64 West Eighty-Fifth Street.

Idiosyncrasy to Quinin.—About six years ago I drove 6 miles into the country to see Miss O. B., aged 14, who had clinical symptoms of malaria. I left for her quinin sulphate in 3 grain capsules. Within two hours a messenger came for me, and I found her with hands, face and feet swollen, rapid, difficult breathing, and a sense of suffocation and weakness. These symptoms were followed by burning and itching all over, especially within the nose and ears. The symptoms gradually disappeared. The patient had taken 3 grains of quinin. One year later the patient took one of the much advertised L. B. Q. tablets for a cold. Within an hour or two she fainted, falling on the floor, and otherwise had symptoms as in the former case. Three years ago a Mobile physician prescribed L. Q. & S. Elixir. Suspecting quinin, she took only 15 drops. Within two hours she was suffering as before. Two years ago she filled some capsules with quinin for her father. She did not taste it, but unconsciously rubbed her lip. The lip swelled as thick as a negro's, and she had slight constitutional symptoms. Two years ago she married and preceding a recent confinement she had several attacks of fever lasting several days each time and resembling malaria. After a number of trials we found the tertian parasite, but gave her no quinin. Following confinement about ten days, I gave her a tonic, containing one-sixteenth grain of quinin to the dose. The first dose produced all the symptoms detailed in the first instance. The patient is a large woman, weighing 200 pounds. As a small child her mother often gave her quinin without any ill effect.—M. A. FORT, M.D., Grand Bay, Ala.

Warning Against Fly Paper.—An exchange mentions that the Public Health Service in Germany has issued a warning against brands of fly paper which contain considerable arsenic and might prove fatal if it fell into the hands of young children. It is advised to use fly paper that has been made with quassia as this would deter children from touching it, while the content of arsenic is less.

SPOILED CANNED FOOD

The necessity for preserving perishable foods from the season when they are produced in overabundance to the months when they are scarce is so evident in these days as to require no justification. In all civilized countries, commercial processes of preservation by heat and by cold have become highly developed and are extensively used. During the past few years, household methods of canning and preserving have been especially urged on economic grounds and have been widely put in practice. As one result it has become a familiar experience in many households that some of the domestically canned foods undergo spoiling after the lapse of a few weeks or months. The commercial canners of food on a large scale have similar experiences and sometimes have cans that are "swelled" or "sour" thrown back on their hands. The question has often been raised as to the dangers to health involved in the spoiling of heat-preserved foods, and now the answer to this question seems to be slowly shaping itself.

When canned goods spoil it is pretty evident that either the heating has not been sufficient to destroy the germs originally present or that the container has leaked and allowed germs to enter with the air. In the latter case decomposition may be caused by yeasts, molds, or the ordinary bacteria of dust; in the former the surviving germs are practically certain to belong to the class of spore-formers. The heat-resistant spore-formers may in turn be divided into two groups, the aerobes and the anaerobes. The spore-forming aerobes found in insufficiently processed canned foods seem to belong largely to the *B. subtilis* or *B. mesentericus* groups, and as yet no injurious effect seems to have been laid at their door. This was perhaps to be anticipated, since organisms of these groups have rarely evinced pathogenic properties and since these aerobic organisms, even if they survive the heating, are not able to develop in hermetically sealed cans.

On the other hand, the spore-forming anaerobes constitute a group, many members of which are highly pathogenic for man and the domestic animals, and some of which, notably *B. botulinus*, have been deti-

nately implicated in cases of food poisoning. It has become increasingly evident that one of the main dangers from botulism in this country is the use of food that has been insufficiently heated in the attempt to preserve it. This has been clearly brought out in Dickson's monograph on botulism,¹ and is further illustrated by an important article in this issue of THE JOURNAL.² The latter investigators lay stress on the fact that in the case reported by them the food was patently spoiled when eaten, and make the somewhat sweeping statement—in the body of the article—that there are "many people who do undertake to salvage canned food which they know to be spoiled or in some stage of decomposition."

The recent studies on botulism appear to establish the interesting fact that there is a wide range of heat resistance among the various strains of *B. botulinus*, and that the organism originally discovered by Van Ermengem and described under this name did not have the same biologic qualities as those manifested by several of the strains of *B. botulinus* isolated in this country. The organism described by Van Ermengem did not grow at 37° C. and had a low heat resistance. The Boise strain isolated by Thom and his associates² has an optimum growth temperature of 37° C., and its spores survive steaming under 10 pounds pressure for fifteen minutes or a temperature of 100° C. for one hour. It is evident that the conditions under which home canning is generally carried out will not always insure the death of these heat-resisting strains of *B. botulinus*.

Thom and his associates are inclined to attach considerable importance to the putrefactive odors emitted by the strain of *B. botulinus* with which they have worked. Earlier writers have described the odor of *B. botulinus* cultures as sharp or butyric, but it is evident that some, at least, of the foods in which this organism has grown (in pure culture) are offensively putrefactive. The practical deduction that is drawn is that canned food presenting physical evidence of decomposition should not be eaten. This seems reasonable enough, and it is a rule that is probably followed instinctively in the majority of cases, although there will doubtless be occasional exceptions.

At the present time, it is plain that botulism is disturbingly frequent in the United States (apparently no case has ever occurred in Great Britain), that food-stuffs canned in the household are especially implicated in the causation of botulism, and that canned foods contaminated with *B. botulinus* usually, perhaps always, manifest physical signs of spoiling. Spoiled canned food has long been recognized as potentially dangerous; we can now estimate certain sources of danger much more precisely.

DO AMERICANS NEED MORE CALCIUM?

Professor Sherman of Columbia University, who has devoted much attention to the inorganic metabolism of man, has come to the conclusion that "the ordinary mixed diet of Americans and Europeans, at least among dwellers in cities and towns, is probably more often deficient in calcium than in any other chemical element."¹ This statement is rendered additionally significant by the fact that calcium constitutes about 2 per cent. of the body weight, a proportion larger than that of any other of the inorganic elements found in the organism. In the case of the growing individual, lime must be provided for the normal development of the bones, which include 99 per cent. of this element. The pregnant mother needs calcium for the rapid increment of the fetus; and during lactation she has a similar requirement for the production of a secretion, milk, which is exceptionally rich in it. The tendency toward a shortage of calcium is not confined to the human species. Forbes,² of the Ohio Experiment Station, has summarized the available information to show that liberal milk production in cattle involves a certain degree of impoverishment of the skeleton in mineral substance; that rations which contain no leguminous roughage are apt to be definitely lacking in mineral nutriment, especially calcium; that the response of heavily producing cows to liberal intake of mineral nutriment is remarkable for its efficiency, it being apparently impossible by any method of feeding entirely to prevent loss of calcium, at least during the early part of the period of lactation, and that the mineral constituents of the skeleton appear to be more readily available for use in milk secretion than are nutrients directly absorbed from the ration.

The seeds, such as are represented by the numerous cereals and their milling products that enter largely into our present day diet, the roots and tubers, and the various meat products probably constitute more than three quarters of the food intake of the average adult American. All of these food materials are comparatively poor in calcium. In referring to this deficiency, McCollum, Simmonds and Parsons³ of the School of Hygiene at Johns Hopkins University regard it as so pronounced that they are of the opinion that "even in those human diets in which such calcium-rich foods as milk are used in fair liberality, the intake of calcium may be still below the optimum, and that a direct addition of this element in the form of the carbonate or lactate might be of distinct benefit in human nutrition except perhaps in those regions where the water is unusually rich in calcium salts."

Oscar Loew long since suggested the addition of calcium salts to the dough from which bread is baked. During the war, several European investigators have formulated similar advice in the belief that even when the daily losses of lime are inconspicuous, long continued deficits in the human calcium balance may be a disadvantage. The average daily calcium requirement has been estimated as a little less than 0.5 gm. per man. One pint of milk will furnish this quantity; but aside from this food, the menu of American homes offers relatively few opportunities to satisfy the human need. Admitting, as we now freely may, that the calcium requirement can be satisfied directly by inorganic salts,⁴ it remains to be determined whether the unfortunate poverty of American diets in milk should not be artificially compensated for. McCollum and his collaborators³ remind us that since civilized man usually adds sodium chlorid to his foods to suit the taste, the shortage of sodium and chlorin in the diet of man presents no problem. They propose that an addition of calcium could be most conveniently made to our foods through the use of a mixture of equal parts of common salt and of calcium carbonate in the kitchen and on the table. This suggestion deserves a sympathetic hearing.

THE ETIOLOGY OF PANCREATITIS

The common association of inflammatory enlargement of the head of the pancreas and disease of the bile tracts appears to indicate a relationship between the two conditions. It has generally been assumed that bile tract disease is primary and that the pancreatic affection is in some way a result or complication of the primary biliary infection. The question, therefore, in the minds of most investigators of this subject has been as to the *modus operandi* of this relationship.

Deaver, of late years, has been the champion, in America, of the theory of the lymphatic transmission of infection from the gallbladder to the pancreas. His conception is based largely on clinical experience and may be stated as follows:

The gallbladder, bile ducts, pyloric region of the stomach and the second part of the duodenum, through their efferent lymph channels, are placed in intimate relation to the head of the pancreas, and it is the head of the pancreas that is most frequently involved in pancreatitis associated with other upper abdominal diseases. The course of infection has time and again been observed at the operating table in gallbladder disease. Inflammation of the gallbladder is followed by enlargement of the cystic lymph glands, periductal lymphangitis, enlargement of the glands at the head and the margin of the pancreas and often of the regional lymph channels at the head of the pancreas. Induration of the head of the pancreas about the common duct is present in 35 to 40 per cent. of disease of the gallbladder. . . . The first stage of chronic pancreatitis is nearly always disease of the pancreatic lymph glands.⁵

5. Deaver: *Pancreatic Lymphangitis*, *Surg., Gynec. & Obst.*, **28**: 433 (May) 1919.

A second theory as to the cause of pancreatitis is based on the results of numerous experiments in which it has been shown that lesions of the pancreas in every way similar to those found in man may be produced in animals by the injection of various substances, particularly bile and the bile salts, into the pancreatic ducts.⁶ The importance of these observations was emphasized by the report of a necropsy by Opie, later duplicated by others, in which a small gallstone in the common duct beyond the point of entrance of the pancreatic duct caused bile to flood the pancreas, producing the typical clinical and pathologic picture of acute pancreatic necrosis.⁷ It should be remembered, however, that frequently in cases of pancreatitis there are no lesions of the bile tracts to account for the pancreatic disease. Thus, Archibald and Mullaly found neither gallstones nor cholecystitis in more than 50 per cent. of thirty-four cases of pancreatitis.⁸

There are, therefore, a number of cases in which none of our current theories of the etiology of pancreatitis are satisfactory. Archibald has recently offered experimental evidence, in the rediscovery of the sphincter of Oddi, which promises to remedy our lack of knowledge in this respect.⁹ Oddi, in 1888, demonstrated the common duct sphincter and studied its physiology, showing that it could be made to contract reflexly in response to a variety of forms of irritation of surrounding viscera with sufficient force to resist the pressure of 50 mm. of mercury. Archibald has confirmed this work, which previously had escaped attention, and added the observation that bile, forced from the gallbladder under pressure which the duct sphincter can be stimulated to resist for a period of minutes, may find its way into the pancreas and there cause almost any grade of pancreatitis the experimenter wishes to produce, from the chronic fibrous type to the fulminating variety with death in a few minutes.

Normal bile is relatively innocuous. As pointed out by Flexner, the mucus of normal bile seems to reduce the irritative properties of the bile salts through its action as a colloid. Bile from which the mucus has been partially or wholly removed, or in which there has been a marked increase in the proportion of bile salts, is relatively toxic to the pancreas and capable of producing rapid, widespread necrosis of the pancreatic cells.

In the light of Archibald's contribution we now seem to know the chemical and mechanical factors necessary to explain satisfactorily the production of all grades of pancreatitis. However, we lack knowledge of the conditions under which these factors are produced. Changes in the composition of the bile may result from the presence of calculi (which themselves

are usually indicative of the presence of low grade infection) and from frank infection. Changes in bile pressure may result from reflex spasm of the sphincter due to hyperacidity or the irritation of gastric or duodenal ulcers; from sudden blocking of the ducts by stone or inflammation, or even from an increase in the rate of bile secretion. The exact relationships here remain to be elucidated.

Archibald takes exception to the idea that pancreatitis ever occurs by retrograde transmission of infection through the lymphatics from the gall tracts to the pancreas. He points out that peripancreatic lymphangitis and lymphadenitis in cases of pancreatitis are probably the results of the pancreatitis rather than its precursors. While the argument seems to be sound, backed as it is by the results of very careful experimental work, it probably would be premature to discard the lymphatic theory altogether. The question deserves at least further study.

THE IMMUNITY OF CITY-BRED RECRUITS

The existence of large bodies of men mobilized in various army camps where they were subject to systematized medical supervision during the past two years has furnished unique opportunities for gathering statistics on an unprecedented scale with respect to the incidence of certain forms of disease. Frequent medical inspection of thousands of men is an uncommon experience, at least on the scale which the preparation for war made possible in the United States. The conclusions afforded by the wealth of data obtainable from such sources are likely to be far more tenable than those drawn from comparatively few cases, however carefully they may be studied.

According to figures recently compiled by Love and Davenport¹ in the Section of Medical Records of the Medical Department of the U. S. Army, it appears that the prevailing rural camps had at least 25 per cent. more cases of influenza, 10 per cent. more pneumonia, 10 per cent. more deaths and 30 per cent. higher admission rate for all sickness than the prevailing urban camps. The army experts conclude, therefore, that in the influenza pandemic, rural troops suffered more than urban troops.

This thesis offers an interesting theme for speculation as to the possible causes of this unlike morbidity. To the person accustomed to hear sung the praises of the healthfulness of country life in America, the figures may come as a surprise. The first hypothesis to account for the recorded facts assumed that recruits coming from densely populated regions are immune from a given disease because they have already had the disease. However, Love and Davenport have pointed out that while such an explanation might apply to measles, it does not apply generally. Thus they state

that cerebrospinal meningitis is scarcely so frequently encountered in early life as to warrant the assumption that the soldiers from the immune areas had acquired immunity from the disease by having had it in their youth. The hypothesis that the immunity is due to the selective elimination of the susceptibles likewise encounters fundamental contradictions.

The most probable suggestion thus far advanced assumes that recruits coming from large cities or other densely populated areas have acquired a general immunity to infectious or communicable disease. In the words of Love and Davenport, it assumes that "any one of the communicable diseases leaves the body in a state of heightened resistance to all microparasites, possibly through a condition of persistent hyperleukocytosis." We shall not enter here into the facts of epidemiology which might be cited in support of such a conviction. Even though it be true that after an epidemic year communities will be exceptionally free from epidemics for a year or two, we shall not be inclined in these days to follow the method, once not uncommon, of exposing children to the danger of certain epidemic diseases for the sake of the subsequent immunity that they might thus acquire.

Current Comment

THE DISCOVERY OF THYROXIN—AN AMERICAN RESEARCH

Persons who deal with so-called "practical" affairs, and employ the routine agencies and materials of their vocations or professions, are singularly prone to overlook the labor involved in perfecting what they utilize so effectively. In the hands of the physician, for example, a seemingly simple manometer is made to tell the story of blood pressure in a few minutes; or a complex chemical compound is prescribed with the assurance that it will accomplish a definite therapeutic purpose—in each case usually without any realization of the scientific efforts preliminary to the final success. Scientific research would receive a more respectful consideration if its necessity for present-day practice were more definitely appreciated. This prelude is the occasion for reference to some details recently published with respect to the discovery by Kendall¹ of the active iodine compound of the thyroid gland. We have already referred in THE JOURNAL to some features of thyroxin, as the compound has been designated briefly, and its potent physiologic properties. The investigation of the chemical constituents of the thyroid was begun by Kendall in 1910 at the pathologic department of St. Luke's Hospital, New York. Thyroxin was first isolated as a chemical entity in December, 1914. Since then many grams have been prepared at the Mayo Foundation laboratories in Rochester, Minn.; in fact, about 33 gm. have been separated from more than three tons of fresh thyroid material. The structural

formula, indicating it to be trihydro-triiodo-oxy-beta-indolpropionic acid was determined in the summer of 1917. Osterberg succeeded in synthesizing thyroxin with its 60 per cent. of iodine in December, 1917; and the synthesis and formula have since been confirmed by Kendall. Minute doses, represented by a few milligrams, of thyroxin show the characteristic stimulation of metabolism in man that thyroid medication is known to bring about. Kendall believes that the active chemical groups in thyroxin are essential to the production of energy in the body.² American science may take pride in the successful outcome of nearly a decade of patient effort in the laboratory directed to the unraveling of the chemical mystery of the potent thyroid. It is a story of persistent trials in the face of many discouraging incidents. The history of thyroxin, in its early chapters now written where all may study it, furnishes an excellent illustration of that "diligent inquiry and laborious, persistent search of truth" which the dictionary designates as research.

THE JOURNAL OF DENTAL RESEARCH

The *Journal of Dental Research*, which has recently begun its career as a journal of stomatology, "devoted to the advancement and dissemination of knowledge pertaining to the mouth and teeth and to their relation to the body as a whole," represents a distinctly new venture in the field of dentistry. Hitherto the publications dealing with this subject have either been accustomed to limit themselves to news and society transactions or been dominated in most cases by the influence of commercial houses. Professor Gies of Columbia University, an ardent champion of independent journalism in science, has remarked in a prefatory note:

Dentistry has been asleep in the field of original literature, narcotized by a system of dominant trade journalism that has been notable in the history of dentistry for commercial efficiency, professional obtundity, and unlimited superficiality—a system of journalism, which, because of its general acceptance and approval by dentists, has demoralized the spirit and impoverished the imagination of dentistry; a system of journalism that has been completely eliminated from respect and influence in every other profession, because of that system's inherent insincerity, unreliability, and selfishness.

Two numbers of the new journal have already made their appearance under the editorship of a group of American investigators whose names guarantee adherence to better ideals. An innovation consists in the publication of abstracts or interpretations of the original matter in each communication so that it may be made also to appeal in "practical terms" to those less well equipped to appreciate the niceties of more highly technical research. Furthermore, the editorial office maintains a Bureau of Information on Dental Research for the assistance of dentists who may wish to avail themselves of knowledge and experience which the board of editors may have. It is hoped to support this worthy undertaking by the establishment of a suitable endowment fund. The *Journal of Dental Research* is practical evidence that a new spirit—a scientific spirit—is now permeating the dental profession in this coun-

try. Until recently, practically all dental journals were of the "house organ" class. Such journals cost the recipient little or nothing, and scientifically are worth just what they cost!

THE TEMPERATURE OF THE SKIN

The temperature of the human body is commonly regarded as one of the constants of the normal organism. Probably no measurement of bodily manifestations or functions is made as frequently by the physician as is the estimation of body temperature with the clinical thermometer. The clinician recognizes, in contrast with most laymen, that the temperature of normal persons as commonly measured may show a diurnal range of variation of approximately one degree, so that one cannot regard it as absolutely fixed; but this is an insignificant variation in comparison with the changes in the heat relations attending febrile diseases. Furthermore, it is understood by those whose vocation calls for frequent measurement of body temperature that the figures recorded in the rectum, axilla or vagina are somewhat higher than those furnished by the thermometer in the mouth where body temperature is usually measured. The differences here referred to are not absolutely large and are taken into account whenever temperature readings are made the basis of clinical judgment. In view of the regularities of temperature in the healthy organism as indicated by such data of internal or deep seated records, it is commonly assumed that the heat losses are distributed rather evenly through the skin. Recent ingeniously contrived measurements of the temperature of the human skin at the Carnegie Institution Nutrition Laboratory in Boston have shown that a change of temperature in the mouth or rectum need not be coincident with or parallel to changes in the temperature of the surface of the body.¹ The skin temperatures were found to range in a normally clothed person all the way from 33 C. (91.4 F.) about the chest and back to 28 C. (82.4 F.) in the region of the ankles. In a nude person exposed to an environmental temperature of 14.6 C. (58 F.) extreme ranges of 10 C. or more were noted, with a rectal temperature of 36.7 C. Even with well clothed persons the temperature of the skin, though one of the most important factors affecting the loss of heat from the body, is, according to the Boston observers, very far from uniform; in fact, differences in the temperature of various localities of from 4 to 5 C. have regularly been observed.

THE CEREBRAL COMPLICATIONS OF MUMPS

Mumps is generally considered a benign infection; but during epidemics it may increase in virulence, and severe complications arise. Of the complications, orchitis, pancreatitis and meningitis are the most important. Meningeal reactions may appear two or three days after the appearance of the swelling, or later as the parotitis is subsiding. Frequently orchitis also develops. The meningitis may manifest itself by increased fever, headache, insomnia, general discom-

fort, and, according to Acker,¹ exceptionally by nausea, vomiting, rigidity of the neck, Kernig's sign, and pupillary changes. The spinal fluid usually is clear, but is under increased pressure and shows a lymphocytosis. Before the advent of spinal puncture, these meningeal symptoms were spoken of as a meningismus of parotitis; but now the occurrence of actual meningitis in the course of mumps is accepted. In a recent study, Haden² remarks that many features of the nervous complications point to an encephalitis, and not simply to a meningitis, and that in most cases the cerebral symptoms are out of all proportion to the meningeal reaction as reflected in the spinal fluid. The occurrence of symptoms of cerebral irritation was noted by Acker, who also records cases with convulsions, monoplegia, hemiplegia or aphasia. Other recent reports seem to confirm the view that the symptoms are due to an involvement of the brain substance; but in the absence of anatomic study of such cases the question remains open. It may be well to recall that, in acute infectious diseases, edema of the brain may produce cerebral symptoms with or without signs of meningeal reaction, and that the spinal fluid in such cases may show no cellular changes. The association of orchitis with meningitis in mumps is of interest in view of the recent report by Latham³ of epididymitis as a complication of epidemic meningitis. He states that some of the mildest cases of meningitis may show marked epididymal involvement. On the basis of Latham's report that in 70 per cent. of the cases with epididymal involvement the meningococcus was found in the blood, we might assume that analogous invasion of the blood takes place in mumps, and that close study of the blood may throw light on its cause.

Outlines for a Birth-Registration Test.—At present only twenty states and the District of Columbia are included in the birth registration area of the United States, and even in those states it has been found that parents and physicians have not attended to this important duty, though the states have been admitted to the list of birth registration states on the basis of 90 per cent. perfect registration. Children's Year workers, in connection with the nation-wide weighing and measuring tests conducted in 1918, found and tested in one town 616 children in which only 112 children were reported as registered; 123 were said to be not registered, and the mothers of 301 children did not know whether the births of their babies had been recorded or not. In another town in which ninety-five children were examined, only seventeen births had been reported. In a Southern state it was found that only 38.4 per cent. of the colored children examined had been registered, while 76.8 per cent. of the white children had been registered. Knowledge of these conditions has led to campaigns for better birth registration, and the Children's Bureau in Miscellaneous Series 12, Bureau Publication 54, has prepared an outline for a birth registration test, giving the plan of canvass step by step and suggesting how to use the results of the canvass, which is to be considered as a necessary part of the community's auditing, at a public mass meeting where the results are announced, by social workers, in talks by physicians and educators, and in connection with other community welfare meetings and activities. A copy of the pamphlet and of the model birth registration law may be had from the Children's Bureau and the Bureau of the Census.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending September 12, there were 6,598 officers in the Medical Corps, a decrease of 578 from the previous week. The Medical Reserve Corps contained 3,414. The total number of physicians discharged since the beginning of the war is 25,646.

Commission of Reserve Officers as Regulars

Congressman Hawley has introduced a bill in the House which provides that any temporary medical officer who entered the active service in the army on or before April 6, 1917, who was at the date of such entrance between the ages of 22 and 32 years and who served with credit throughout the war, shall on application be regularly commissioned a first lieutenant in the permanent Medical Corps of the Army, and said commission shall be dated as of the date of the entrance of such medical officer into the active service.

Army Reorganization Bill

Following is the exact text of the Army Reorganization Bill, proposed by the War Department and now before Congress, as it relates to the Medical Corps:

"The Medical Department shall consist of the Medical Corps, the Dental Corps, the Veterinary Corps, and the Army Nurse Corps. The Medical Corps shall consist of one major general; two brigadier generals; one hundred and twenty-three colonels; two hundred and eleven lieutenant colonels; nine hundred and twenty-two majors; one thousand seven hundred and fifty-five captains; eight hundred and seventy-eight first lieutenants; one hundred and twenty-five master hospital sergeants; one hundred and twenty-five hospital sergeants; one thousand seven hundred and fifty sergeants, first class; two thousand seven hundred and fifty sergeants; one thousand two hundred and fifty corporals; one hundred and twenty-six mechanics; one thousand seven hundred and sixty-nine wagoners; one thousand one hundred and two cooks; five thousand three hundred and thirty-four privates, first class; and ten thousand six hundred and sixty-nine privates. The Dental Corps shall consist of nineteen colonels; nineteen lieutenant colonels; fifty-nine majors; two hundred and seventy-eight captains; four hundred and eleven first lieutenants; three hundred and fourteen second lieutenants; thirty-four sergeants, first class; and forty-four sergeants; one wagoner; three hundred and forty privates, first class; and six hundred and eighty privates. The Veterinary Corps shall consist of five colonels; five lieutenant colonels; fifteen majors; sixty-eight captains; one hundred and one first lieutenants; seventy-six second lieutenants; one hundred and ninety-four sergeants, first class; four hundred and eighty sergeants; ninety-six horseholders; two hundred and forty corporals; forty-eight saddlers; fifty-four mechanics; nine hundred and sixty stable sergeants; ninety-eight wagoners; ninety-six cooks; eight hundred and sixty-five privates, first class; and one thousand seven hundred and thirty privates. The President is hereby authorized to call into active service, and to retain as long as the conditions of the service require, officers of the Veterinary Reserve Corps, with their consent, in such numbers that, including the number of officers of the Veterinary Corps herein permanently authorized, the total number of veterinary officers on active duty at any time during peace shall not exceed in the respective grades mentioned eleven colonels; nine lieutenant colonels; thirty majors; one hundred and thirty-six captains; two hundred and two first lieutenants; and one hundred and fifty-two second lieutenants. The enlisted strength for the Veterinary Corps provided in this section shall be varied in accordance with the number of draft and riding animals in the Army so that the total number of enlisted men shall not exceed forty for each thousand animals, and the proportions of enlisted men in the various grades shall be approximately as set forth in this Act. The Army Nurse Corps shall be constituted as now provided by law. The general officers herein provided for shall be appointed from officers of the next lower grade in the Medical Corps."

Major-Gen. M. W. Ireland, the Surgeon-General, recently appeared before the Senate Committee on Military Affairs and offered numerous objections to the above provisions. He pointed out that the bill does not provide for any Surgeon-General to act as chief of the Medical Department, and also that it makes no mention of the enlisted personnel of the Medical Department. He also showed that it makes no provision for granting commissions on the basis of examination by a board of medical officers, which fact he much regretted. He declared in favor of promotion by seniority, rather than by selection and was much opposed to the selective method, declaring that it was destructive to the morale of the officers. The Surgeon-General also favored allowing the Medical Department to have general supervision over the procurement and transportation of the supplies for the department. He

said that the various branches of the Medical Corps cooperated very effectively during the war. In reply to questions as to whether he favored granting army rank to nurses, General Ireland said that he thought it would be "wholly wrong" to do so.

312 South Lafayette Boulevard and is open daily from 2 to 4 in the afternoon and from 7 to 8:30 in the evening.

MARYLAND

Personal.—Dr. Edgar B. Friedenwald, Baltimore, who served as major in the Medical Corps since May, 1917, has received his discharge and has returned to his home.—Dr. Charles A. Reifschneider, former superintendent of the University Hospital, Baltimore, has arrived at Camp Merritt, N. J., from overseas, where he served with the Medical Corps.

Eye Clinic for Schoolchildren Proposed.—Dr. Benjamin W. Hazell has offered to equip an eye clinic for the children of the poor of Baltimore, if the city will consent to furnish space, heat and janitor service. Wholesale optical houses will supply glasses at cost and Dr. Hazell and other opticians, will give their services free. Diseased conditions of the eye will not be treated, but will be referred to a proper dispensary. The suggestion has been referred to the committee on hygiene of the board of school commissioners.

Foreigners in Baltimore for Study.—Dr. Juan C. Segovia, director-general of the health board of San Salvador, Salvador, and founder of the Institute for Contagious Diseases in San Salvador, has arrived in Baltimore to take a two years' course in bacteriology and parasitology at the Johns Hopkins University.—M. Biraud, a former officer in the French army, whose home is at Poitiers, France, has been announced as one of the recipients of fourteen scholarships to American universities given to French students by the former "American Army Students of France," and will come to the Johns Hopkins Medical School.

MASSACHUSETTS

Semcentennial of State Health Board.—The Massachusetts Department of Health celebrated the fiftieth anniversary of its establishment at the State House, September 13. Among the chief speakers were Dr. Henry P. Walcott, Boston; Dr. William H. Welch, Baltimore; Asst. Surg. Allan J. McLaughlin, U. S. P. H. S., and Sir Arthur Newsholme of England. The health commissioner, Eugene R. Kelly, Boston, presided, and the visitors were welcomed on behalf of the state by the governor.

Personal.—Dr. Herman Morris Adler, Chicago, formerly assistant professor of psychiatry in Harvard University, has been appointed professor of criminology and head of the department of social hygiene, medical jurisprudence and criminology in the medical department of the University of Illinois, Chicago.—Dr. Louis W. Croke, Dorchester, medical director of the U. S. Shipping Board, Recruiting Service, has resigned.—The cross of the Legion of Honor was officially presented to Dr. Morton Prince, in the Hall of Flags of the State House in recognition of his distinguished service in promoting Franco-American cooperation during the late war.

MISSOURI

Child Clinic Opened.—September 1, a child clinic, with Dr. Frank C. Neff in charge, and a dental clinic for children and adults was opened as a portion of the outpatient department of the Research Hospital, Kansas City.

District Society Organized.—Physicians from Clinton, Caldwell, Daviess, Platte, Ray and Clay counties met in Cameron, August 14, and organized the Twelfth Council District Medical Association, electing Dr. John D. Musgrave president, and Dr. John J. Gaines secretary, both of Excelsior Springs.

NEW YORK

Personal.—Dr. William L. Munson, Granville, who has recently returned from military service, has been reassigned to duty as sanitary supervisor of Clinton, Essex, Warren, Washington counties and part of Franklin County.—Dr. John A. Conway, Hornell, has returned from service and has resumed his duties as sanitary supervisor for Steuben, Tompkins, Schuyler, Chemung, Tioga and Broome counties.—Dr. Frank Overton, sanitary supervisor for Long Island, has been temporarily assigned to Albany for the last four days of each week as sanitary supervisor for Columbia, Greene, Rensselaer, Albany, Schoharie and Schenectady counties, during the absence of Dr. Charles C. Duryee on special duty in connection with health officers' courses and scoring of health activities of cities.—Dr. Matthias Nichols has been appointed head of the advisory committee of the International Exposition of Municipal Equipment, Grand Central Palace, New York City.

New Hospital for Insane.—Governor Smith broke ground, September 13, for a new state hospital for the insane at Marcy, near Utica. The site of the institution comprises 930 acres of the best farm land in the state and the legislature has authorized the expenditure of \$2,000,000 on the buildings, which will house 3,000 patients. Abundant provision has been made for a water supply and sewage disposal at Marcy so that a setback such as that encountered in the attempt to establish a state hospital at Mohansic may be avoided. The governor in his address told of plans that are being made by the hospital commission for a state psychopathic hospital in New York City, which will be the research department for the state hospitals for scientific studies into the causes and treatment of insanity, and which will also be used for the temporary care of the less serious cases of mental disorders. Among the other speakers were Dr. Charles W. Pilgrim, Poughkeepsie, and Dr. Walter B. James, New York City.

Health Activities.—In connection with the International Exposition of Municipal Equipment it is proposed to establish a permanent health center which will serve to demonstrate the kind and amount of apparatus and equipment necessary for such an undertaking.—The West Chester County Chapter of the American Red Cross has established a model child welfare station in the interior of an auto-truck and has sent this exhibit into a number of towns of West Chester County.—An infant welfare exhibit and baby show was given at Gouverneur Fair during the week of August 19, under the auspices of Dr. Stanley W. Sayer, sanitary supervisor of the district, and Miss Winifred Noone of the child hygiene division of the state department of health.—A health meeting was held on the Tonawanda Indian Reservation, August 27, together with a survey and clinic.—A tabulation of the reports of health officers for 1916 has been compiled from which it appears that during that year, the average amount paid per capita for health work was 19 cents.

—The board of health of Elmira has authorized the establishment of a general clinic in Elmira to include child welfare work and measures against tuberculosis and venereal disease.—Dr. J. Henri LaRoque, health officer of Plattsburg, is having fitted up a suite of offices in the city health department which will accommodate clinics for tuberculosis, infant welfare and venereal diseases.—Dr. Virgil D. Sellick, health officer of Glens Falls, is making arrangements for venereal disease clinics.

New York City

Annex to Beth David Hospital.—A drive to raise \$100,000 for the enlargement of Beth David Hospital was begun, September 7, and will be continued for three weeks. The proposed annex to the building will add 125 beds and will bring the capacity of the hospital up to 175. A donation of \$5,000 toward the fund from the Ladies' League of the hospital and \$500 from Jacob D. Cohen were announced.

Health Department Moves to New Headquarters.—By September 25, the headquarters of the department of health, now at Centre and Walker streets, will have been removed to Pearl and Park streets, across the street from the Municipal Building. This removal was necessitated by the expiration of the lease on the building at Centre and Walker streets and the refusal of the comptroller and the board of estimate to consider the exorbitant increase in rental demanded by the landlord. The new headquarters will be used temporarily until the specially built structure for which plans are now being prepared can be erected. It is hoped that this new building will be ready for occupancy in about a year.

NORTH CAROLINA

Hospital Opened.—The Lawrence Hospital, Winston-Salem, was opened, September 1. The building is the old Thompson home which has been remodeled for hospital purposes and now has accommodation for twenty-five patients. The institution is in charge of Dr. Charles S. Lawrence and G. Carlyle Cooke.

Personal.—Dr. Frank M. Register, Jackson, health officer of Northampton County for two years, has resigned to accept a position as chief of the bureau of epidemiology of the state board of health at Raleigh.—Dr. Sidney E. Buchanan, Concord, has been elected full-time health officer of Cabarrus County.—Dr. Willur B. Robertson, Tarboro, health officer of Edgecombe County, has resigned and has been temporarily succeeded by Dr. William W. Green.

PENNSYLVANIA

State Meeting.—The annual meeting of the Medical Society of the State of Pennsylvania will be held in Harrisburg, September 22 to 25.

Personal.—Dr. Nelson E. Newbury, Scranton, has been appointed director of the city health department.—Dr. Julius H. Comroe has been appointed chief of the genito-urinary dispensary at York.—Dr. Edward E. Marsh, Centralia, recently returned from service abroad, has been elected superintendent of the Pottsville Hospital.—Dr. George W. Stimson, Pittsburgh, Major, M. C. U. S. Army, who has been serving in France as otolaryngologist with Evacuation Hospital No. 31, has returned from overseas.—Dr. James R. Montgomery, Bloomsburg, recently returned from active service in France, was, August 15, appointed county medical officer, succeeding Dr. Samuel B. Arment, resigned.

Philadelphia

Personal.—Dr. P. Gaskell Skillern, Jr., who was senior medical officer on the U. S. S. *Orizaba* while the ship was commissioned by the French government, has sailed for Denmark where it is reported, he is to marry Miss Lisa Valentiner of Koge.—Dr. Alonzo Englebert Taylor of the University of Pennsylvania will give the Lane Lecture before the Stanford University Medical School, California, in December.

New Department of Public Health.—The new Philadelphia charter has so affected the department of public health and charities as to separate the health work from its charity functions. Under the terms of the new law, there is a department of public health of which the director of public health is the head, appointed by the mayor with the advice and consent of the council. He is to have the power to appoint an assistant director, and such other officers and employees as may be provided for. The department has the care, management, administration and supervision of city activities relating to public health, including hospitals, control of housing and sanitation, and collection of vital statistics. The board of health is to consist of the director of public health, as president, and two other members, who shall be appointed by the mayor with the consent of the council. Two of the members of the board must be physicians.

The Alvarenga Prize.—The College of Physicians of Philadelphia announces that no award of the Alvarenga Prize has been made for 1919, and that the next award of the prize, being the income of one year of the bequest of the late Señor Alvarenga amounting to about \$250, will be made, July 14, 1920, provided an essay deemed by the committee of awards worthy of the prize shall have been offered. Essays entered for competition may be on any subject, but cannot have been published; must be typewritten and if in a language other than English must be accompanied by an English translation and must be received by Dr. Francis R. Packard, secretary of the College, 19 South Twenty-Second Street, Philadelphia, on or before May 1, 1920. Each essay must be sent without signature, but must be marked with a motto accompanied with a sealed envelope having on its outside the motto and inside the name and address of the author. The successful essay or a copy of it is to remain in the possession of the college. Other essays will be returned on application within three months after the award.

TEXAS

Personal.—Dr. A. P. Harrison, Corsicana, has been appointed state director of the bureau of rural hygiene, succeeding Dr. Platt W. Covington, Austin, resigned.—Dr. Marshall E. Parker, Anderson, has been reappointed state registrar of vital statistics.—Dr. Victor E. Bonelli, Corpus Christi, has been appointed city school physician of Fort Worth.—Dr. Lane B. Cooke has been appointed city health officer of Dallas.

Quarantine Merger.—September 1, Robert L. Wilson, Surg., U. S. P. H. S., in charge of the quarantine station at Galveston, took over the equipment of the till quarantine station at the city of Galveston and with this transfer the dual system of quarantine service of the port of Galveston ceased to exist. The quarantine properties of the city were sold to the United States for \$900,000. The property was valued at \$110,000. It is estimated that by the transfer of the property to the United States, there will be a saving for the state of more than \$200,000.

Cooperation in Health Work.—Dr. Charles W. Goddard, Highland, president of the state board of health, August 27, completed the draft of the contract whereby the state of

Texas and the International Health Board offer \$5,000 to each of four counties appropriating a similar amount for a county health department with a whole-time health officer. Special provision is made for active work to stop soil pollution and the combating of hookworm. The county health officer is to be appointed by the state health officer as also are his assistants in sanitary work.

WISCONSIN

Medical Building for Ashland.—Dr. John M. Dodd, Ashland, has awarded a contract for a new office building which will cost \$25,000 or more and will be equipped with seven new offices, each of which will be occupied by a physician or a dentist.

Personal.—Dr. Fred T. Nye, Beloit, has retired after forty years of active practice, and will move in a short time to Irvington, Ala.—Dr. Herman H. Albers, Allenton, was elected president of the First District Medical Society at its meeting held near Waukesha, August 20.

CANADA

Educating Young Physicians.—The Ontario Medical Council adopted the following resolution at its recent meeting: "That all physicians who had had only one year of practice before enlisting in the army, be compelled to take a six months' postgraduate course, and that the Ontario government give a grant of \$500 to cover such expenses."

Medical Council Elects Officers.—At the recent meeting of the Medical Council of Canada, Dr. J. C. Connell of Kingston, Ont., was elected president; Dr. Alex. MacNeill of Summerside, P. E. I., vice president, and the following were reelected: Sir Thomas Roddick, honorary president; Dr. R. W. Rowell, Ottawa, registrar, and Mr. F. H. Chrysler, general counsel.

Hospital News.—The Kingston General Hospital will build a special wing for the treatment of tuberculous patients. This is in connection with the hospital enlargement scheme of Queens Medical Department.—The city council of Niagara Falls has apportioned \$50,000 toward a 100-bed hospital to cost \$100,000.—The county council of Huron County, Ont., has approved a grant of \$50,000 for hospital purposes.

Personal.—Dr. Theodore A. Lomer, D.S.O., medical officer of health for Ottawa, has returned from overseas.—Dr. George S. Strathy, Toronto, has returned from overseas.—Major George D. Porter, Toronto, has resigned his position as commanding officer, Divisional Laboratory No. 2, after three and a half years' service.—Dr. Robert E. Wodehouse, M.O.H., Fort William District for Ontario, has been made an officer of the British Empire.

Council for Combating Venereal Disease.—The Canadian National Council for combating venereal disease has recently been organized. The aims and objects being to combat venereal diseases by whatever means seem desirable, to encourage and assist the dissemination of a sound knowledge of the physiologic and moral laws of life in order to raise the standard both of health and conduct; to cooperate with existing associations, to seek their approval and support and to give advice when desired in order to provide the constituent social measures which are basic in the solution of this problem; to promote such legislative, social and administrative forms as are relevant to the foregoing aims and objects; to provide accurate and enlightened information as to the prevalence of these diseases, and as to the necessity for early treatment; to promote the provision of greater facilities for their treatment and to increase the opportunities of medical students, practitioners and trained nurses for the study of these diseases.

GENERAL

Warning.—Dr. Eugene M. Stansbury, Vermilion, S. D., writes to warn the profession against a man claiming to represent a supply company of St. Louis, Mo., selling auto supplies to members at factory prices. He offers two years' service for \$90, calling only on physicians. A letter addressed to the concern at St. Louis, Mo., is returned, stating that there is no such company nor such a street address.

Dietitians Elect Officers.—At the annual meeting of the American Dietetics Association held in Cincinnati, last week, Miss Lulu Graves, professor of home economics in Cornell University, Ithaca, N. Y., was elected president; Miss Ruth Wheeler, Baltimore, and Miss Margaret Deveyers, Mount Sinai Hospital, Cleveland, were made vice presidents; Miss

E. Geraghty, New Haven, Conn., was elected secretary, and Miss Margaret Sawyer, American Red Cross, Washington, D. C., treasurer.

Military Surgeons' Meeting.—The annual meeting of the Association of Military Surgeons of the United States will be held at the Hotel Statler, St. Louis, October 13 to 15. Commissioned officers of the Army, Navy, Public Health Service and National Guard, members of the Medical Reserve Corps and physicians who have been commissioned and subsequently honorably discharged from the service are eligible to membership and will be welcomed at this meeting of the association.

Hospital Association Election.—At the twenty-first annual meeting of the American Hospital Association held at Cincinnati, September 8 to 13, under the presidency of Dr. Andrew R. Warner, Cleveland, the following officers were elected: president, Dr. Joseph B. Howland, Boston; president-elect, Lewis R. Baldwin, superintendent of the University Hospital, Minneapolis; vice presidents, Drs. Henry E. Webster, Montreal; Richard G. Brodrick, San Francisco, and Miss Margaret Rogers, St. Louis, and treasurer, Mr. Asa A. Bacon, superintendent of the Presbyterian Hospital, Chicago.

Graduate Medical Fellowships for Negroes.—Mr. Julius Rosenwald of Chicago is offering six fellowships to negro graduates in medicine by which they may pursue advanced studies in the fundamental medical sciences under favorable conditions. Each fellowship stipend will be \$1,200 to pay the student's transportation to and from the institution in which he will work as well as his laboratory and tuition fees, books and living expenses. The medical schools in which these fellowships will be available will be selected by a special committee under the direction of the General Education Board, New York City.

Bequests and Donations.—The following bequests and donations have recently been announced:

For the enlargement of the Winston-Salem, N. C., Hospital, an addition of \$50,000 to the gift of her late husband, by Mrs. Reynolds, Permeant fund of the Infant's Hospital, Thomas Morgan, Roth Memorial Building, Boston, \$6,000 by the will of Clara Morgan Roth.

To improve and extend the workshop of the Saginaw, Mich., Anti-Tuberculosis Hospital, a donation of \$500 by E. C. Merston, John H. Barker, Boston, \$250,000, contingent on the expiration of annuities, by the will of John W. Grace, Cambridge.

For a maternity hospital at Hastings, Neb., \$40,000 and for the Mary Lanning Memorial Hospital, Hastings, Neb., \$400,000 by the will of W. H. Lanning.

Michael Reese Hospital, Chicago, \$84,000, on the death of Mrs. Emma Rosenthal, by the will of Albert Dallemard, Kenosha, Wis., Hospital, \$16,000, by the will of Elizabeth M. Moore.

Pathometry of the Influenza Epidemic.—The subcommittee on pathometry of the influenza epidemic, of the special committee on statistical study of the influenza epidemic which was reorganized at the meeting of the Section of Vital Statistics of the American Public Health Association in December, 1918, held meetings at Columbia University, New York, September 19 and 20. The discussion at the preliminary meetings of the committee brought out a rather confusing lack of agreement as to the effects of preventive measures and of modes of treatment on the form of the epidemic wave and as to the kinds and character of statistical data available. The work and recommendations of the other three registration and tabulation subcommittees will, it is hoped, result in presenting data that are uniform and better adapted to comparative study toward discovering the quantitative relationships which this epidemic holds in common with other epidemics.

Executive Committee of National Tuberculosis Association Meets.—The executive committee of the National Tuberculosis Association met at the Russell Sage Foundation in New York City, September 13, at which time a survey of the tuberculosis situation in the United States was presented which shows that the country is face to face with a condition more menacing to the people than actual warfare. This survey shows an annual death rate of 150,000 from tuberculosis in the United States and more than 1,000,000 active cases in the nation. To combat the spread of the disease the committee asserts that an intensive national campaign is necessary. Funds for this campaign will be sought by a ten day sale of Red Cross seals, beginning December 1. The total of the state budgets will be more than \$6,500,000. In the course of the discussion, it was pointed out that the death rate of 150,000 a year from one preventable disease means the sacrifice of more lives than the United States Army lost in the year it was actively engaged in the war. An educational campaign has been formulated which will be extended to every part of the country, with the view of impressing on the people that tuberculosis is preventable and curable and

of inducing them to take measures to protect themselves. Plans to care for all afflicted persons will be pressed and a special effort will be made to search out incipient cases.

Workers in Venereal Disease Campaign Wanted.—The recently created Interdepartmental Social Hygiene Board of the United States government is in need of a number of specially trained men and women to complete its organization. The United States Civil Service Commission has announced examinations for the following positions: chief of division for scientific research, \$3,500 to \$4,500 a year; chief of division for educational research and development, \$3,500 to \$4,500 a year; educational assistant, \$2,800 to \$3,600 a year; chief of division of relations with states, \$3,500 to \$4,500 a year; chief of division of records, information and planning, \$3,500 to \$4,500 a year; supervising assistant and inspector, \$2,800 to \$3,600 a year; field agent, \$1,800 to \$3,000 a year. All positions are open to both men and women. Applicants for these positions will not be given scholastic tests in an examination room but will be rated on their education, experience and writings. Published writings of which the applicant is the author will be submitted with the application. For most of the positions a thesis on one of a number of given subjects will be accepted in lieu of published writings. The receipt of applications will close, November 4. Detailed information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or from the secretary of the United States Civil Service Board at the postoffice or custom house in any of 3,000 cities. The law creating the Interdepartmental Social Hygiene Board provides for the cooperation of the War and Navy Departments and the Public Health Service of the Treasury Department for the prevention, control, and treatment of venereal diseases. The duties of the board as set forth in the act are: to recommend rules and regulations for the expenditure of moneys allotted to states for the use of their respective boards or departments of health in the prevention, control, and treatment of venereal diseases; to select universities, colleges, or other suitable institutions which shall receive allotments for scientific research for the purpose of discovering more effective medical measures for the prevention and treatment of venereal diseases; to recommend such general measures as will promote correlation and efficiency in carrying out the purposes of the act; and to direct the expenditure of certain moneys appropriated by the act.

FOREIGN

Mortality Increase at Riga.—It is reported from Riga that the mortality during April last was eight times as large as in pre-war times. During June there were 359 deaths caused by starvation.

Meeting of the Italian Orthopedic Association.—The tenth Congress of the Italian Society of Orthopedics will be held at Bologna, October 19 and 20, 1919. The subjects for discussion will be Prostheses and the Treatment of Pseudoarthroses. By special invitation, Prof. Carlos Francioni will deliver a lecture on "The Morphologic Evolution of the Human Organism in the First Stage of Life." In connection with the congress there will be held an exhibition of orthopedic apparatus and instruments.

Mortality in Spain.—The decrease in the population of Spain has begun to cause serious concern. During February last the average birth rate in the most important cities was 2.12 per thousand and while the mortality rate was 2.42. In twenty-nine of the provincial capitals the number of deaths exceeded the number of births. These capitals included every important city in Spain. At Madrid, the death rate was 2.55 and the birth rate was 1.84. Over one-fourth of the deaths in the various cities were among infants under 5 years.

American Medical School in Paris.—The project for the establishment of the American School of Medicine in Paris took definite shape at the meeting held recently in the office of Charles F. Beach, an American lawyer in Paris. In addition to a number of laymen, Drs. Tuffier of the Academy of Medicine, Dehelly, Alexis Carrel, Edmond Bornet, and other noted physicians and surgeons of Paris were present. The new school is to be entirely postgraduate in character, and will be under the joint direction of American and French physicians.

New Public Health Act in South Africa.—The parliament of the Union of South Africa has adopted a comprehensive bill known as the Public Health Act, 1919, chapter four of which deals with venereal diseases and applies to most of the

health measures which have been adopted in the United States with the exception of the compulsory report of cases to the health authorities. Compulsory treatment of all cases is provided and any person who infects another knowingly is declared guilty of an offense. Advertisement of nostrums is prohibited.

Deaths in the Profession Abroad.—Dr. A. Tamburini, professor of psychiatry at the University of Rome and director of the psychiatric clinic, aged 71. He was elected president of the Italian Società freniatrica in 1895, and has been constantly reelected since, and has always been called on to preside at the Italian psychiatric congresses. He was long a member of the national public health council and recently published a large work on the care of the insane by the state in different countries. For forty years he has been director of the *Rivista sperimentale di Freniatria*.—Dr. C. Vignolo-Lutati, instructor in skin and venereal diseases at the University of Turin, and a noted writer on these subjects.

The Monaco Congress for Physiotherapy.—Great preparations have long been under way for this international gathering at Monaco in October which aims to extend the knowledge and application of the natural resources of the allied and neutral nations, the mineral waters and muds, the seashore, climate, altitude, sunlight, etc. There are to be special congresses and sections devoted to thalassotherapy, hydrology, heliotherapy, hygiene, spas, climatic resorts and touring, alpine climbing, etc. France and Italy in particular are making efforts to present an instructive display of their natural resources in these lines. French is the official language of the thalassotherapy congress and the only theme appointed for discussion is "Medical and Surgical Tuberculosis at the Seashore," but other communications on other subjects are to be presented.

Medical Gatherings in the Scandinavian Countries.—The *Ugeskrift for Læger* comments that after the long suspension on account of the war, medical congresses are now being held in the Northland with new zeal and profit. The surgical and dermatologic congresses were held at Christiania in July. In August the tuberculosis specialists, the pediatricists and the internists each held a special congress at Copenhagen where in September was also held the Nordiske hygiejnske Kongres. The Medical League of Sweden and the similar organization in Denmark held their meetings also in August, as already mentioned elsewhere. Many physicians attended several of these meetings in turn. At the Congress for Internal Medicine the registration was 215, the attendance including eighty physicians from Sweden, seventy from Denmark, forty-six from Norway, eighteen from Finland and one from Iceland. Almost the whole range of internal medicine was represented in the forty-two communications presented. They included a number of interesting reports on research by the younger workers.

LATIN AMERICA

Nurses' School in Colombia.—At the Women's University, just established at Medellín, Colombia, there will be given a two years' course in nursing.

Study of Influenza.—Dr. Antonio Cueto Vázquez, the secretary of the commission on infectious diseases, has been sent to the United States by the government of Cuba to study the treatment of influenza as practiced in this country.

Typhoid Epidemic in Bogotá.—It is reported from Bogotá, Colombia, that a serious epidemic of typhoid has appeared in that city. It is said that as many as fifteen patients had been taken in one day to the Hospital of San Juan de Dios.

New Pasteur Institute in Mexico.—On recommendation of the president of the superior board of health, the government has decided to open a Pasteur Institute in the city of Chiapas, in view of the fact that a large proportion of rabies cases proceed from that state.

Superior Board of Health Organized in Nicaragua.—The government has just appointed the personnel of the superior board of public health, which will consist of members of the medical profession of the city of Granada. Dr. Juan José Martínez was appointed president of the board.

New Tropical Medicine Society in Mexico.—A medical association has just been organized at Villahermosa, Mexico, under the title of *Sociedad Tabasqueña de Patología Tropical*. Its object will be to study the diseases which affect that region. The following officers have been elected: president, Dr. Jesús Flores, secretary, Dr. Odilio Aguilar C., assistant secretary, Dr. Eduardo Castellanos G., and treasurer, Dr. Dógenes López R.

PARIS LETTER

PARIS, Aug. 28, 1919.

The Transfusion of Blood in Shock Produced by War Wounds

At a recent meeting of the Société de chirurgie de Paris, Drs. Lacoste, Lartigaut and Piqué, hospital surgeons of Paris, communicated the results that they have secured from the transfusion of blood in thirty-six cases of war wounded. They were not in position to study the density of the blood, a research recommended by Richet, but they undertook a blood count after the method of Depage and Govaerts, and they studied especially the arterial tension with the aid of Pichon's oscilometer.

Lacoste, Lartigaut and Piqué made a blood examination in thirteen wounded men, eight of whom presented a deficiency of blood cells such as is considered by Depage and Govaerts as symptomatic of a serious hemorrhagic condition and as beyond the reach of ordinary therapeutics. These patients presented at the same time clinical symptoms extremely indicative of serious posthemorrhagic anemia, and yielded a mortality of 25 per cent. However, in this series of thirteen patients there were five in whom the hemorrhagic syndrome was at least as frank and just as alarming as in the other cases but who nevertheless did not present an appreciable diminution in the number of blood cells. Among these five patients there were no fatal cases. Therefore, from the practical standpoint, in case a patient is clinically hemorrhagic it is well to make a blood cell count. In the event that the deficiency reaches limits considered by Dupage and Govaerts as alarming, the surgeon has an added reason for blood transfusion. But one should not conclude that the maintenance of a normal or approximately normal blood count for the first few hours is a sufficient contraindication for transfusion, and that it justifies one in relying on a satisfactory improvement in the blood picture. In more than a third of the cases there is a discrepancy between the blood picture and the serious indications of acute anemia. Nor should the indications for blood transfusion be based solely on the result of the blood cell count but rather more on a study of arterial tension.

Out of approximately 1,600 grave untransportable cases, Lacoste, Lartigaut and Piqué found only thirty-six cases in which transfusion was indicated, thirty-three of which were due to hemorrhagic and three to nonhemorrhagic shock. In seven cases of this series they performed preoperative transfusion on moribund men who were pulseless, presented no arterial tension, and were insensible to artificial serums, such men as would have died at the beginning of the war before the eyes of the surgeon, whereas, today, many such patients, thanks to blood transfusion, can be put into condition to sustain an operation successfully. Immediate post-operative transfusion performed in order to improve the general condition of the wounded to whom the shock of an unavoidable immediate operation has come in addition to traumatic shock were also seven in number. These transfusions permitted the extension of the indications for surgical procedure in wounded men on whom formerly an operation could not have been attempted.

The other transfusions were late post-operative. These concern wounded men who, under the influence of artificial serums, camphorated oil, caffeine, etc., had made a temporary gain but relapsed into a state of shock. The transfusion supervening at the time when the first medication has become ineffective may then save some patients. Others, moreover, do not react to the serums and present a progressive lowering of the arterial tension with a decrease in the maximal and minimal pressure, a fall of the oscilometric index, reduction of the differential pressure of the range of oscillation; in such cases transfusion is instituted without delay.

Repatriation of Prisoners of War

The international committee of the Red Cross has addressed a letter from Geneva to the interallied conference in Paris calling attention to the question of repatriation of prisoners of war. The letter refers to the difficulties encountered at the time of the repatriation of the prisoners from enemy countries interned in the states of the central empires. It states that if the repatriation cannot be begun immediately, at least plans for the repatriation ought to be worked out at once in order that the actual transportation may be begun as soon as the peace treaty is ratified and be an accomplished fact by the time winter sets in. Such provision is especially indicated in view of the various difficulties that may arise on account of the large number of prisoners and the great distances some of them must be transported.

Interallied Medical Mission to Poland

An interallied medical mission consisting of Col. H. S. Cumming, representative of the Medical Corps, U. S. Army, as director; Professor Castellani; George S. Buchanan, an officer of the British Public Health Service, and Dr. Visbecq, chief surgeon of the Medical Corps of the French Army, has just left Paris for Warsaw. At the request of the Polish government this mission has been sent to Poland to study the problem of typhus fever and other contagious and epidemic diseases that are making great ravages in Poland at this time. This mission was organized by the Red Cross League.

The American Red Cross in France

The American Red Cross has just published a report of its work in connection with the American army in France. It received in its hospitals 89,539 wounded or sick, who required 1,110,000 days of hospitalization. The average cost of a day's hospitalization, including medical and surgical care, has been 9.78 francs. At the time of the signing of the armistice the American Red Cross had under its control twenty-two hospitals with 14,326 occupied beds.

The American national committee has just made a gift of \$32,742.95 to the American Red Cross, to create at Paris an American hospital for wounds of the face and jaw. Soldiers disfigured by war wounds will be admitted here for treatment.

The Optical Institute

In a previous letter I referred to the plan of establishing an optical institute with a view to restoring in France the manufacture of optical lenses and optical instruments in general, which of late years has passed into the hands of the Germans (THE JOURNAL, Dec. 23, 1916, p. 1954). This institute has become an actual fact. It will work in the interest of all French manufacturers of opticians' supplies; it will not be conducted for commercial profit but solely for the purpose of advancing optical science and the optical industries for the common welfare. The forms of activity of this new scientific institute will be: (1) a training school of optics; (2) a laboratory of research and experiment, and (3) a professional school for advanced study.

The school of optics will train experts in the manufacture of optical goods. M. C. Fabry, at present professor of general physics at the Faculté des sciences de Marseille, has been selected as the head of the new institution. Mr. Lucien Poincaré, rector of the University of Paris, has evinced an especial interest in the institute and has expressed his intention of requesting a professional chair of optics at the Sorbonne.

The laboratories will comprise a research department in which the instructors of the school may conduct their theoretical and practical researches with relation to the various kinds of glass, optical instruments and opticians' accessories, and a department for the study of manufactured products or any matters of importance submitted for examination into by the institute. These laboratories will serve likewise for the training of students. The purpose of the professional school will be to train workers in glass, opticians and mechanicians who shall be preeminently qualified.

The Origin of Shock

At the meeting, July 15, of the Academy of Science, Professor Quénu presented an interesting report of some investigations of Dr. Pierre Deltet, professor of clinical surgery at the Paris School of Medicine, on the toxicity of lacerated muscles from the standpoint of the pathogenesis of shock. Deltet undertook numerous experiments. He removed the crushed and lacerated muscles of 121 animals, including rabbits, rats, mice, frogs and cats, and injected the filtrate of these tissues in 213 animals. The toxic effects were noted in every instance, and the animals developed polypnea, disappearance of reflexes, and coma, frequently ending in death. Recovery is possible even after coma sets in. The early deaths which supervene in from a few minutes to six or seven hours after injection, without the animal coming out of the coma, seem to be due to the intoxication of the cerebral and bulbar nervous centers. The retarded deaths which take place after the animals have recovered from the coma are due mainly to liver alterations. Muscular tissue infected by the streptococcus, the staphylococcus, the proteus or the *B. pyocyaneus* appeared less toxic than the aseptic tissue.

The toxic accidents are always of the same type, but they vary greatly in intensity. The same character of dose may produce insignificant results or may have a mortal effect.

Gray rats and frogs, which are eminently carnivorous, proved much more susceptible than guinea-pigs, which are herbivorous. These facts developed by experiment led to the suspicion that the strong meat diet of the soldiers was one of the causes of the frequent severe symptoms of shock during the war.

LONDON LETTER

LONDON, Aug. 27, 1919.

Punishment of Pharmacists Under the Venereal Diseases Act

The venereal diseases act of 1917 marked a new departure in English law by rendering penal the treatment of venereal diseases by any one but a qualified physician. Formerly any quack or other person, however ignorant, could treat any disease with impunity. The only liability was that in case of death they might be tried for manslaughter, but, as a matter of fact, even in the case of Christian scientists who had undertaken to treat serious disease which proved fatal, no conviction has ever been obtained. In the present case a pharmacist and his assistant were prosecuted. The former advertised in the *Daily Telegraph* "prescription 606," which he described as a "bad blood tonic." In a pamphlet which he issued he wrote: "Even syphilis in most instances can be cured by the patient himself, provided he is told at the outset what remedy to take." His formula was stated to consist of potassium, mercury, sodium and iron iodids, sarsaparilla and other drugs. A police inspector went to his shop and asked if the "606" advertised was for venereal disease. He was told it was, and bought a box of tablets. The assistant told a police sergeant that his "606" was the best he could have and better than arsenaphen. The jury found both defendants guilty. The principal was sentenced to four months imprisonment and the assistant to six weeks. The judge said he took into consideration the fact that this was the first case of the kind in which a prosecution took place.

Tuberculosis Among Ex-Soldiers and Sailors

The interdepartmental committee appointed by the minister of health and the minister of pensions to consider the steps for the provision of residential treatment for discharged soldiers and sailors suffering from tuberculosis, and for their reintroduction into employment, especially on the land, has issued its report. The number of ex-service men invalidated out of the services on account of tuberculosis, or afterward found to be suffering from tuberculosis attributable to, or aggravated by, conditions of service, amounts to about 35,000. Of these, 22,000 have received or are receiving residential treatment, which has often been for far too short a period. The committee feels that the problem of the tuberculous ex-soldier or sailor is only one aspect of the national problem of dealing with tuberculosis. The best possible use should be made of all existing means of treatment, and then these means should be expanded and improved as rapidly as possible. The priority of treatment hitherto afforded to ex-service men should continue. There is serious shortage of accommodation in existing sanatoriums and hospitals for the treatment of tuberculosis. The number of beds in the United Kingdom is 19,500. If allowance be made for the number required for women and children, the number available for the male adult population is only about 10,000. The accommodation should be increased immediately. The question of using existing army hutsments for the treatment of tuberculosis presents many difficulties. The hutsments are not likely to provide satisfactory accommodation, but it is possible that the best army hospital huts, and others of similar construction, would make satisfactory sanatoriums, at any rate for temporary use. With regard to treatment, it should take place in three stages. First should come the sanatorium, next the colony where treatment is continued but where training is the main objective, and lastly the permanent village settlement, where permanent employment is afforded under medical supervision.

Rats as Carriers of Spirochaeta Icterohæmorrhagiae

Major A. G. R. Foulerton, officer in charge of the hygiene department of the Army Medical College and health officer for East Sussex, has presented a report to the city corporation of an investigation undertaken at their instance on the protozoal parasites of the rat, with special reference to spirochaetal jaundice in man and the London rat as a natural reservoir of that disease. During the last four years, Japanese workers have shown that the rat is a carrier of the microbes of spirochaetal jaundice and rat-bite fever, which, though harmless to the rat, is pathogenic to other

animals, including man. Rat carriers of the microbe of jaundice have been found not only in Japan but also in Algeria, America, Belgium, France and Tunis. Examination of 101 London rats caught showed that four were carriers of the spirochete of jaundice.

Physicians Increase Their Fees

Since the war the cost of living has increased more than 100 per cent. A certain increase of physicians' fees has naturally taken place, but it has not been universal or uniform. The British Medical Association thinks that 50 per cent. is the least that physicians' fees should be increased, considering not only the increased cost of living but also that of drugs, instruments and gasoline. Some time ago the association circularized local authorities asking that medical salaries should be increased by 33 1/3 per cent. Panel physicians are at present receiving a bonus varying from 15 to 30 per cent., according to their total incomes.

The Influence of Alcohol on Manual Work

For the Medical Research Committee an investigation on the influence of alcohol on manual work and on neuromuscular coordination has been carried out by Dr. H. M. Vernon and Dr. Major Greenwood. The conclusions arrived at are as follows: Small doses of alcohol, well within the limits of what would be deemed by all moderation, do not sensibly affect the speed of performance of such semiautomatic operations as typing a memorized passage or setting down and adding a row of figures on a mechanical calculator, but gravely depreciate the accuracy of performance. Two glasses of port wine in a person accustomed to drink a glass of wine have this effect when the wine is taken with food. Less than this is sufficient to produce a result if taken on an empty stomach. Should the task set be very familiar to the subject, the foregoing conclusion does not hold. Such small doses of alcohol did not exert any measurable effect on the number of mistakes in either the typing or the adding test made with a speed of performance to which the subject had become familiarized by long practice. None of the experiments bring out any effect on the slow additions or typings, experiments which were made at a speed to which those experimented on were quite accustomed.

Peccoliar Method of Suicide

An inquest was held in York on a woman, a physician and latterly a patient in a lunatic asylum. Last November the deceased told a visiting relative that she had attempted to kill herself and ought to be dead, since she had stuck a needle into her heart. The medical superintendent was informed, and found two apparently simple pin pricks below the left breast. The patient had been suffering from melancholia and grew very much better and her delusions left her. Nothing more was heard of the needles until recently, when, after a few days' illness the lady died. The necropsy disclosed one needle sticking through and a second one into the walls of the heart together with signs of acute inflammation.

Marriages

WILLIAM LACEY EDMUNDSON, Major, M. C., U. S. Army, Denver, to Miss Dorothy Peacock Hummwell, at Wilmette, Ill., August 10.

LEON ALBERTI D'AMORE to Miss Pauline Jaramillo, both of Las Vegas, N. M., at Trinidad, Colo., August 30.

CARL HENRY DAVIS, Milwaukee, to Miss Elizabeth Greene Upham of Killbuck, Wis., September 6.

CLAUDE GOLDWIN SARGES, Lenoir, Ga., to Miss Anna Belle Mills at Monticello, Fla., August 13.

JAMES ALD WARD, Baltimore, to Miss Linda Belle Henneock of Birmingham, Ala., September 8.

LAWRENCE DEYANO MILLER, Toledo, to Miss Elizabeth Hamby of Cleveland, August 28.

HARRY FREY, Rock Island, Ill., to Miss Helen M. Somers of Grinnell, Iowa, September 2.

HENRY J. DEHAVY, to Miss Fannie Halsh, both of East St. Louis, Ill., September 3.

MERTON O. ARNOLD, Chicago, to Miss Uretil V. Semell of Dixon, Ill., June 20.

OTTO JOHN JURA to Miss Blanche Rezanka, both of Chicago, recently.

Deaths

BENJAMIN FRANKLIN CHURCH, Redlands, Calif.; College of Physicians and Surgeons, Baltimore, 1888; aged 61; a member of the Medical Society of the State of California, and in 1917 chairman of the eye, ear, nose and throat section of the society; president of the San Bernardino County Medical Society in 1917-1918; once president of the Travis County and Kaufman County (Texas) medical societies, and president of the Los Angeles Academy of Medicine; a specialist in diseases of the eye, ear, nose and throat; formerly dean of the faculty and professor of ophthalmology and otology in the College of Physicians and Surgeons, Los Angeles; who had been under treatment in Los Angeles for mental troubles for eight months; leaped from the window of his physician's office, September 2, and was instantly killed.

BOSWELL P. ANDERSON, Colorado Springs, Colo.; University of Virginia, Charlottesville, 1868; Washington University Medical School, Baltimore, 1869; aged 72; a Confederate veteran; at one time president of the Colorado State Medical Society; for more than forty-five years physician and surgeon to the Colorado State Blind and Deaf Institute; president of the staff of St. Francis' Hospital, Colorado Springs; for ten years chief surgeon and thereafter consulting surgeon to the Colorado Midland Railroad; died at his home, August 25, from angina pectoris.

JOSEPH MANUEL ELLIOT, New Orleans, Tulane University, New Orleans, 1889; aged 59; a member of the Louisiana State Medical Society; professor of clinical medicine in the New Orleans Post-Graduate School of Medicine; chief of staff of the department of internal medicine at Charity Hospital, New Orleans, and visiting physician to the hospital for twenty-five years; vice president of the City Bank and Trust Company, New Orleans; died at his home, August 30.

GEORGE HERBERT RICHARDS, Orange, N. J.; New York Homeopathic Medical College, New York City, 1885; aged 66; formerly president of the Orange board of health and of the board of education; a lieutenant in the Medical Reserve Corps of the Army, and discharged in December, 1917; president of the board of trustees of the Homeopathic Hospital of Essex County, N. J.; died at his home, September 9, from heart disease.

WALTER CHEYNE, Sumter, S. C.; College of Physicians and Surgeons in the City of New York, 1891; aged 51; a specialist in urology; secretary of the Sumter County Medical Society in 1916, and president in 1918; at one time secretary of the South Carolina Medical Association, and first president of the National Association of State Secretaries; one of the founders of Toumey Hospital, Sumter; died at his home, August 13, from cerebral hemorrhage.

JOHN ANDERSON JOHNSTON, Capt., M. C., U. S. Army, Manila, P. I.; University of Pennsylvania, Philadelphia, 1893; aged 40; a specialist in bacteriology; president of the Manila Medical Society of Sciences; died in the Department Hospital, Manila, August 1, from acute dilatation of the heart and chronic myocarditis following influenza.

GEORGE ROBERT CURRAN, Mankato, Minn.; University of Michigan, Ann Arbor, 1892; aged 50; local surgeon of the Chicago and Northwestern system; surgeon to St. Joseph's Hospital; formerly first lieutenant and assistant surgeon in the Second Minnesota Infantry; died at his home, September 1, from heart disease.

JOHN H. ALEXANDER, Greensburg, Ind.; Medical College of Ohio, Cincinnati, 1874; aged 90; a resident of Decatur County for sixty-one years; physician to the state Odd Fellows' Home for many years; also president and secretary of the Decatur County Board of Health; died at his home, September 4.

JOSEPHINE ELIZABETH SMITH, Chicago; Rush Medical College, 1917; an intern at Cook County Hospital until Feb. 28, 1919; who passed the examination of the National Board of Examiners in October, 1917; died in the Washington Boulevard Hospital, Chicago, August 5, from acute lymphatic leukemia.

WILLIAM WATTS, Toledo, Ohio; University of Michigan, Homeopathic Medical School, Ann Arbor, 1878; aged 65; formerly major and surgeon, Sixth Infantry, Ohio National

* Indicates "Fellow" of the American Medical Association.

Guard; a member of the staff of the Toledo Hospital; acting coroner of Lucas County in 1917; died at his home, August 31.

Robert Aloysius Biechele, Wooster, Ohio; Western Reserve University, Cleveland, 1888; aged 52; once president of the Stark County (Ohio) Medical Society; president of the Citizen's National Bank and the Wooster Electric Company; died at his home, September 3, from angina pectoris.

George Ellsworth Paff, Chicago; Indiana University, Indianapolis, 1908; aged 35; formerly of Gary, Ind.; died in the Grace Lutheran Sanatorium for Tuberculosis, San Antonio, Texas, about August 20, from tuberculosis.

Charles D. Ricker ★ Capt., M. C., U. S. Army, Fabens, Texas; Maryland Medical College, Baltimore, 1902; aged 43; died in the Walter Reed General Hospital, Tacoma Park, D. C., August 4, from myocarditis.

Samuel Wesley Rimmer ★ San Saba, Texas; Kentucky School of Medicine, Louisville, 1890; aged 55; once president of the San Saba County Medical Society; died at his home, recently, from angina pectoris.

Herbert B. Perry, Benson, Ill.; Jenner Medical College, Chicago, 1876; aged 60; a member of the Illinois State Medical Society; died in Brokaw Hospital, Bloomington, Ill., August 25, from nephritis.

Thomas Noel White, Spring Garden, Ala.; Medical College of Georgia, Augusta, 1890; aged 80; surgeon of the Nineteenth Alabama Cavalry, C. S. Army, during the Civil War; died at his home, August 23.

Edward Malcolm Bruce, Chicago; Hahnemann Medical College, Chicago, 1891; aged 58; professor of internal medicine in his alma mater; died at his home, September 8, from cerebral hemorrhage.

Cyril Wickfield Sager, Titusville, Pa.; American Medical College, Pilectie, St. Louis, 1885; Hahnemann Medical College, Philadelphia, 1894; aged 57; died on his farm at Beaverdam, Pa., August 24.

Lee Mason Barney, Elkhart, Ind.; Northwestern University Medical School, Chicago, 1889; aged 53; who had been blind since 1913; died at his home, September 4, from cerebral hemorrhage.

Abijah Marvin Allen, Adrian, Mich.; University of Michigan, Ann Arbor, 1861; aged 85; assistant surgeon of the Seventh Michigan Infantry during the Civil War; died suddenly, August 26.

William S. Stillé ★ Parkersburg, W. Va. (license, West Virginia, act of 1881); aged 69; died at his home, August 26, from pneumonia, three weeks after an operation for the removal of gallstones.

Halton I. Jessup, Philadelphia; Hahnemann Medical College, Philadelphia, 1884; aged 57; a specialist in ophthalmology; died at his home, September 3, from cyclonephritis.

Martin F. Coomes, Louisville, Ky.; Louisville (Ky.) Medical College, 1873; aged 72; died in St. Joseph's Infirmary, Louisville, August 28, a short time after a surgical operation.

George L. B. Rounseville, Mattoon, Ill.; Bennett Medical College, Chicago, 1883; aged 74; died in Cook County Hospital, Chicago, August 15, from valvular heart disease.

Burtell Thomas Landers, Oklahoma City; American Medical College, Eclectic, St. Louis, 1890; aged 75; a practitioner for forty-two years; died at his home, August 29.

Frank H. Williams, Spring Lake Beach, N. J.; University of Pennsylvania, Philadelphia, 1874; aged 67; died at his home, August 29, from cerebral hemorrhage.

Frank L. Hoag, Elk Rapids, Mich.; Detroit College of Medicine and Surgery, 1892; aged 51; died in Chicago, September 8, from chronic interstitial nephritis.

Walter May Fitch, Chicago; Rush Medical College, 1885; aged 57; died at his summer home in Twin Lakes, Wis., September 11, from heart disease.

John Joseph Barth ★ Chicago; Rush Medical College, 1914; aged 33; died in the Alexian Brothers Hospital, Chicago, August 29, from septicemia.

James Riggs Burkhart, Davenport, Iowa; Keokuk (Iowa) Medical College, 1898; aged 43; died at his home, September 8, from heart disease.

H. Walter Murlless ★ Guilford, Conn.; Louisville (Ky.) Medical College, 1893; aged 50; died at his home, August 24, from sarcoma.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORIES, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

THE LUCAS LABORATORIES' PRODUCTS

THE JOURNAL has received several inquiries about the products put out by the Lucas Laboratories, Incorporated, of New York City. A typical inquiry is that received from Dr. F. A. Jewett of Brooklyn, who writes:

"The enclosed circular is sent out to the medical profession by Dr. William Lucas, 287 W. 70th St., New York. What do you know of this man and his methods?"

William H. Lucas was graduated by the Medical College of Ohio in 1875 and was licensed in 1897. He is not a member of his local medical society. The products put out by the Lucas Laboratories are for intravenous use, and their method of exploitation indicates that the concern is less interested in the science of therapeutics than it is in taking commercial advantage of the present fad for intravenous medication. THE JOURNAL has protested editorially against the unnecessary use of the intravenous administration of drugs, and the abuse of this method of drug-giving prompted the Council on Pharmacy and Chemistry recently to emphasize the danger of indiscriminate intravenous medication.

The products of the Lucas Laboratories, Inc., have not been examined either by the A. M. A. Chemical Laboratory or by the Council on Pharmacy and Chemistry. The composition of these products is essentially secret, which in itself should be sufficient to deter physicians from using them. Of course, in accordance with all the tenets of orthodox nostrum exploitation, "formulas" are furnished. Even the crude hieroglyphics that used to be palmed off on the medical profession by nostrum exploiters under the guise of "graphic formulas" are outdone by the Lucas Laboratories in publishing the alleged formulas of its preparations. If we, as physicians, knew more chemistry, the Lucas Laboratories would not find it profitable to publish such ineffable nonsense as that which characterizes their "literature." For instance:

"Luvain' Arsans (Plain)" is said to be: "Di hypo sodio calcio phosphite hydroxy arseno mercuric iodide." The first part of this "formula" might stand for sodium and calcium hypophosphite. The remainder is meaningless except that it suggests (but does not insure) the presence of arsenic and mercury iodide.

"Luvain' Arsans, Nos. 1, 2 and 3."—"Meta hydroxy iodide sodio arseno mercuric dimethyl lenzo sodio arsenate, at oxy sodio tartaria sulpho disbenyl hydrazin." Who can venture even a conjecture as to the possible significance of this?

"Luvain' Crocospophite."—"Ammonio hydroxy calcio sodio hypo-phosphite arsenous pentoxy iodide." While the name suggests crocote, the "formula" gives no hint of this. It might refer to hypophosphites of ammonium, calcium and sodium with iodide of arsenic. Whether arsenous (trivalent arsenic) or arsenic (pentavalent arsenic) iodide or both are intended, is a question.

"Luvain' Hexacod."—"Hexa methylenepyro catechin mono methyl amino ether glycerite." By moving these syllables around like the old "fifteen puzzle" they can be arranged to represent hexamethylenamin and monomethyl ether of pyrocatechin (or gniaeol), having the "glycerite" left over.

It is futile to discuss the therapeutic claims made for the various preparations put out by the Lucas Laboratories. One might as profitably discuss the therapeutic claims made for "Perma" or "Paine's Celery Compound" for the exploitation of the latter products is on just as high a scientific plane as the exploitation of the "Luvain" nostrums. The proposition offered to physicians by the Lucas Laboratories, Inc., is an insult to the intelligence of the medical profession. Not that the products themselves are necessarily any worse or

any better than many others offered for intravenous use; the selling methods are more crude, that is all.

The facts are, we have entered a new cycle of nostrum development. The unscientific mixtures for oral administration that characterized so large and disreputable a part of the proprietary medicine business of the past two or three decades, are giving way to equally unscientific mixtures for intravenous use. The dangers of the older nostrums are accentuated in the newer by the added element of risk that is inseparable from intravenous therapy. Add to this the temptation to the physician in the way of more substantial fees which, legitimately enough, may be charged when intravenous administration is called for, and the menace of the new style nostrum becomes evident. THE JOURNAL can only reiterate the warning that intravenous therapy should be employed only when most positively indicated. Further, because of the danger that is inseparable from this method of drug administration, physicians should be doubly careful to see that products employed for intravenous use come from firms of unquestioned scientific standing.

CASE'S RHEUMATIC SPECIFIC

Last week THE JOURNAL recorded the issuance of a fraud order against Jesse A. Case of Brockton, Mass. On account of the false and fraudulent representations made by Case for his nostrum he was denied the use of the United States mails, Aug. 18, 1919. Very shortly thereafter Case made application for the revocation of the fraud order on the grounds that he had entirely discontinued his fraudulent mail-order nostrum business and was now engaged in an entirely different business of a legitimate character. In addition to his personal application, Case filed the following affidavit:

"I, Jesse A. Case, being first duly sworn, depose and say that the business heretofore conducted by me, (i. e.) the selling of a rheumatism treatment which the Fraud Order issued against me on August 22, 1919, was designed to suppress has been discontinued and will not be revived any time in the future and that any remittances hereafter received for said treatment will be returned to the sender."

The postal authorities have notified THE JOURNAL that as Case's fraudulent business no longer exists and Case has sworn that he will not revive it and will return to the senders any remittances that may come to him in the future for his "rheumatism cure" it is believed that the ends of justice will be met and satisfied by revoking the fraud order. The order has been revoked.

"DEATH FROM RHUBARB LEAVES DUE TO OXALIC ACID POISONING"

To the Editor.—The case of death after eating rhubarb leaves (THE JOURNAL, Aug. 23, 1919, p. 627) deserves, I think, some further discussion. It seems to be established that oxalic acid is one of the most active of the acids. It is generally stated in the textbooks that, unlike the other corrosive acids, such mild alkalis as potassium acid carbonate (saleratus) or sodium acid carbonate (baking soda) cannot be used as antidotes, as the oxalates of these metals are almost as poisonous as the free acid. They are, however, not likely to be as corrosive. Oxalic acid is apparently a very frequent product of both animal and vegetable metabolism. It is almost always found in the form of an oxalate, generally calcium oxalate. This is an almost constant constituent of urinary sediments, and very frequent in leaf and root tissues. In the latter it generally occurs as bundles of fine needles in special cells. The corn of the Indian turnip or our forests (*Crisman triphyllum* (L.) Torr.) contains a large amount of these crystals, and the extremely irritating property of the corn is due to their mechanical action.

There is no likelihood that calcium oxalate will act as a specific poison. It is highly insoluble in water, and even in many dilute acids. The standard antidote has been lime. "Scrape the ceiling with a fire-shovel in an emergency" has

been for more than half a century a classic in toxicology. I am inclined to the opinion that in the cases of poisoning by rhubarb leaves which have lately been reported, including the case in THE JOURNAL, the mechanical action of the calcium oxalate is the cause. The patient suffered an abortion, and it is worth while to inquire whether this was not brought about by the irritation of the pelvic viscera by the crystals. It is not likely that the feebly acid gastric juice would be able to dissolve this material.

The original article from which the abstract in *Chemical Abstracts* (11:2374, 1917) is printed (quoted by THE JOURNAL in the bibliography) is not accessible to me, but the process is given in the abstract, and it consists first in heating the vegetable matter with strong hydrochloric acid, which dissolves all the oxalates. The calculation is made to pure oxalic acid, but there is, of course, no reason to believe that this exists as any plant. When plant structures have a distinct sour taste, as in the case of species of *Oxalis*, it is generally assumed that potassium acid oxalate is present. The figures in the article to which you call attention give for rhubarb 32 gm. per thousand of material as prepared for cooking. Now 1000 gm. are more than 2 avoirdupois pounds, and this amount would according to the analysis yield about 50 grams of oxalic acid, but, as I have remarked above, much of this is probably in the form of calcium oxalate. The standard authorities give the fatal dose of oxalic acid as rather large, from 50 to 60 grains; and even supposing that the whole of the oxalic content of the rhubarb leaf was the free acid, about 2 pounds of it would be required to furnish a poisonous dose.

I am inclined to think, therefore, that the mechanical irritation of the insoluble sharp crystals is the cause of the death.

HENRY LEFFMANN, M.D., Philadelphia.

[COMMENT.—There is ample evidence opposing the mechanistic theory of our correspondent. Most of the cases of poisoning recorded followed the eating of rhubarb stems, but a number have resulted from eating the leaves. Fortunately, most of the victims recovered. The reports of the fatal cases show that there were violent vomiting and diarrhea followed by coma and death. Epistaxis with noncoagulability of the blood has been observed, and an abortion before death reported. The symptoms (especially the noncoagulability of the blood) are such as would be expected from the ingestion of moderate quantities of oxalic acid or soluble oxalates, by those having an allergic manifestation toward oxalic acid.

In the case which has been best studied (Poisoning by Rhubarb Leaves, *Lancet* 1:847 [June 2] 1917; *Pharm. J.* 98:413 [May 12] 1917; THE JOURNAL, June 23, 1917, p. 1928; June 30, 1917, p. 1954), oxalic acid was detected in the internal organs, but no evidence was presented to show the presence of calcium oxalate crystals or other mechanical irritant in the viscera. The physician who made the necropsy attributed the death to coma consequent on oxalic acid poisoning. The chemist who examined the internal organs of the deceased also analyzed rhubarb leaves from the same field as those eaten by the victim and found about 10 grains each of potassium oxalate and calcium oxalate to the pound. Van Italic and Lemkes believe that the toxic dose of potassium oxalate, usually stated at from 30 to 75 grains, is actually much less. If this is true, the contention that the amount ingested in the case recently reported was not sufficient to cause death is much weakened. Our correspondent thinks it unlikely that the feebly acid gastric juice would be able to dissolve calcium oxalate (an inert substance), thus transforming it into soluble oxalates (poisonous substances). In the A. M. A. laboratory, 1 gm. of calcium oxalate was treated with 500 c.c. of 0.2 per cent. hydrochloric acid at the laboratory temperature for four hours. About 0.2 gm., or 20 per cent., was rendered soluble. Doubtless the amount would be greater at the temperature of the body.

The acidity of the Indian turnip and some other plants is due to the mechanical action of calcium oxalate crystals. The irritating properties are destroyed by cooking. Wiley believes that the calcium oxalate crystals are dissolved in the cooking process but, since the acidity of the Indian turnip is low, it is more probable that the heat destroys the crystalline structure of the raphides by depriving them of their water of hydration. In the cases of rhubarb poisoning it is

clear that the stems and leaves which had been eaten were cooked. It is reasonable to suppose that the same effect on the oxalates might be obtained by cooking rhubarb as by cooking the Indian turnip. Further, there is no evidence that crystals of calcium oxalate have been detected either in the vomitus or internal organs of the poisoned victims, or in the cooked rhubarb which they had eaten. Until this evidence is forthcoming, the theory of mechanical irritation must rest in the domain of the unproved.—Eo.]

NECROPSIES AT BELLEVUE HOSPITAL

To the Editor:—I have read with interest Dr. Francis Carter Wood's article on "The Relation of Pathology to Medicine" (THE JOURNAL, Aug. 23, 1919, p. 569). I may be pardoned for having focused attention on that passage which inquires: "If the Mayo Clinic and the General Memorial Hospital of New York succeed in obtaining a permit [for necropsy] in over 90 per cent. of deaths, why does Bellevue Hospital obtain only 7 per cent. and many other institutions only from 20 to 30?"

As far as Bellevue Hospital is concerned, the interrogation is misleading, without design on Dr. Wood's part, of course. I have investigated the necropsy figures of Bellevue Hospital covering the past seven years and I find that, with the exception of the chaotic period of 1918, when the percentage fell to 7.6, and the year 1915, when it dropped to 14 without any cause now recallable, our necropsies obtained by consent vary between 25.4 and 36 per cent. of the total number of deaths, excluding from the computation, of course, those cases which fall under the jurisdiction of the chief medical examiner's office—with these we neither dare nor care to meddle—and the unclaimed dead—with these we have nothing to do since, when an individual dies in Bellevue Hospital and is without friends or relatives, the unclaimed body passes thence to the custodianship of the commissioner of public charities, who now exercises full authority over its disposal—whether it is to be given to the anatomic board for scholastic purposes or buried in Potter's Field without dissection. In these two ways between 1,200 and 1,500 bodies every year automatically pass beyond all possible control of the hospital authorities at the very instant that death occurs.

I should also like to point out that in Bellevue Hospital the average total number of deaths yearly is 3,540, while in the Mayo Clinic the average is about 254, and in the General Memorial Hospital it is lower still, so that it is scarcely fair to compare the necropsy statistics of the two smaller institutions with those of the second largest general hospital in the Western Hemisphere. Compared, however, with the Boston City Hospital—the only really large American institution whose necropsy figures are available to me—the Bellevue record is indeed creditable, the Boston institution, with an average yearly death rate of 1,830, securing only about 7 per cent. of necropsies.

In Bellevue Hospital there are two outstanding obstacles to the securing of consent for necropsy, namely, the ignorance and prejudice of relatives or their inaccessibility, and the interdiction of the Jewish religion. In fact, these two obstacles unite to render it impossible to secure permission for postmortem examination in no small proportion of deaths; and yet, in spite of these formidable impediments, Bellevue Hospital secures by consent an average of about 400 necropsies yearly. All of them are performed by the accredited pathologists of the institution. Moreover, a large part of the work of the medical examiner's office and of the medical assistant to the district attorney of the county of New York is carried out in the postmortem rooms of Bellevue Hospital. Attendance on every necropsy thus performed is open to our visiting and resident staff. The total number of necropsies from these two sources seldom, if ever, falls below 1,200 a year, at least 30 per cent. of the number coming from the wards of Bellevue Hospital. In short, the student of pathologic anatomy can see as much postmortem material, perhaps more, within the walls of Bellevue Hospital than in any other institution in the English speaking world, embracing not only the average run of cases,

but also an extraordinarily wide range of material representing the pathology of crime and violence.

Although at Bellevue Hospital we are by no means satisfied with our work in pathology, we nevertheless feel that not only is the hospital doing its share to keep alive an interest in pathologic anatomy, without which there is no intelligent medicine, but also the institution is playing no mean part in the development of the newly organized institute of legal medicine of which the city of New York has reason to be proud and for which it should be thankful.

DOUGLAS SUMMERS, M.D., New York.
Director of Laboratories, Bellevue and Allied Hospitals.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

WAR RISK INSURANCE

To the Editor:—I am at present an officer in the Medical Reserve of the U. S. Army. My hospital internship was incomplete at the time of the armistice. Consequently I have not been called to active service. Is it possible for me now to take out the Army insurance policy which was granted to all officers and men on active service, and at the same rates? If so, can you give me any information as to how to proceed to do so? I shall appreciate anything you may do for me by way of advice in this matter.

J. R. SCOTT, M.D., Kerkhousen, N. Y.

ANSWER.—The War Risk Insurance Act provides that insurance shall be granted to every commissioned officer and enlisted man and to every member of the Army Nurse Corps (female) and of the Navy Nurse Corps (female) when employed in active service under the War Department or Navy Department, upon application to the Bureau and without medical examination. It further provides that such insurance must be applied for within 120 days after enlistment or after entrance into or employment in the active service and before discharge or resignation. As the inquirer was never in the active service, he is not entitled to war risk insurance. Even if he was at one time in the active service, he cannot now, after separation from active service, take out a war risk policy.

INTRAVENOUS USE OF ANTIMONY TARTRATE

To the Editor:—In THE JOURNAL, Aug. 23, 1919, p. 645, I find an abstract of an article entitled "Bilharziasis Treated by Intravenous Injection of Antimony Tartrate," which appeared in the *Journal of Tropical Medicine and Hygiene*. Please inform me whether the authors give in this article the composition and the method of preparation of the solution of Antimony Tartrate used, and also give such facts concerning the technique, as amount administered, interval between injections, and occurrence of reactions.

L. A. KINSELL, M.D., Philadelphia.
Lieutenant, M. C., U. S. Navy.

ANSWER.—The apparatus in use at the Khartoum Civil Hospital for the intravenous injection of antimony tartrate, both for bilharziasis and also for leishmaniasis, is as follows: 1. Two small 50 c.c. Bohemian flasks one containing a sterilized solution of antimony tartrate (antimony and potassium tartrate, U. S. P.), $\frac{1}{2}$ grain to 20 minims of distilled water (20 grains to the ounce), the other containing a sterilized solution of physiologic sodium chloride solution for dilution purposes, each labeled with their respective contents. 2. Two record syringes (glass with metal plungers), a small one of 20 minims, and a large one of 10 c.c. The same size needles are used for both syringes; they should be fine (hypodermic) and sharp with platinum iridium tips (a fine sharp needle is a very important requisite). 3. A small sterilizer, two or three small beakers, crucibles and watch glasses should be ready for holding and mixing solutions, and for containing the solution of antimony and the physiologic sodium chloride solution ready for use. With a skilful assistant to compress the veins, a tourniquet is unnecessary. A prominent vein of the arm is chosen, preferably not the median basilic at the elbow as it is in relation to the brachial artery; any prominent vein, however, will do; sometimes a vein at the back of the hand is conveniently conspicuous when others are not. This small operation should

be done with much care. It is absolutely necessary to inject the antimony tartrate solution inside the lumen of the vein, or phlebitis and necrosis result. The skin is sterilized with ether or alcohol; iodine may be used, but it has a tendency to obscure the veins on dark skins. Treatment commences with the injection of $\frac{1}{2}$ grain in about 40 or 50 minims of physiologic sodium chlorid solution. Injections take place every other day, equal parts of the antimony solution and the physiologic sodium chlorid solution being used when larger doses are reached. The dose is increased by $\frac{1}{2}$ grain every injection until 2 or 2½ grains have been reached, and this is maintained (in the case of boys of 10 or under, 1½ grains is the maximum dose employed). The total quantity of antimony injected would be 20 or 25 grains, according to circumstances. If more than 25 grains are required, the surplus needed should be reserved for a second course. When the dose of antimony tartrate is 1½ grains or 2 grains (sometimes before), a cough immediately on injecting indicates that the antimony is already in the pulmonary circulation, and shows that the drug is both rapid and far reaching in its action.

BIOGRAPHIC NOTES ON FUCHS, TSCHERNING AND LANDOLT—THE ORIGIN OF SPECTACLES

To the Editor.—I require some biographic notes about Dr. Ernst Fuchs of Vienna and Drs. H. M. E. Tscherning and Edmond L. Landolt of Paris. As it is impossible to find much about European celebrities in works of reference after 1914, I would appreciate any information you can give me about these men. What I particularly wish to know is whether they are still living, and what professional positions they now occupy.

2. I have a recollection of having read somewhere in recent years of excavation in Greece, Rome or Egypt of spectacle frames, or some other indication that the ancient peoples were acquainted with the use of eyeglasses. Can you supply me with the reference.

W. H. BATES, M.D., New York.

ANSWER.—1. No information regarding any of these men is available since 1916; but it is not likely that any of them have died since they are all of sufficient note to have received general mention regardless of the war. The following data are available concerning the last positions which they have occupied:

Fuchs.—The "Biographisches Lexikon" for the year 1901 lists Fuchs as follows: "Fuchs, Ernst, zu Wien, geb. daselbst June 14, 1851, studierte . . . war 1876 bis 80 Assistent bei Arlt, 1880 bis 85 Prof. der Augenheilk. in Lüttich, und ist seit 1885 Prof. der Augenheilk. (als von Jaeger's Nachfolger). Litterar. Arbeiten . . . Lehrbuch der Augenheilkunde (his jetzt in 7 Aufgäbe erschienen und in 6 Sprachen übersetzt)." He retired in 1915.

Tscherning.—The "Annuaire médical" lists: "Tscherning, 1887, Directeur du laboratoire d'ophtalmologie à la Sorbonne, oculiste de l'Institution nationale des Sourds-Muets (maladies des yeux) de 1 h. à 3 h. mardi, samedi, rue du Méziers 15."

Landolt.—"(Edmond) Zurich, 1869, Paris, 1874. O. medecin-oculiste consultant à l'Institution nationale des jumeaux aveugles. Clinique des maladies des yeux, tous les jours de midi à 2 h. St. André des Arts, 27 excepté le samedi, rue Volney 4."

2. We know of no recent excavations of spectacle frames. There are historical data, however, for the statement that lenses were used by old persons to distinguish small print in China and in Europe in the thirteenth century, from 1260 to 1367 A. D. These medieval glasses are said to have come from Turkestan, and historians are inclined to believe that they reached Turkestan from India, where they existed at the end of the twelfth or the beginning of the thirteenth century. On a tombstone in a Florentine church appears the inscription: "Here lies Salvino d' Armati of Florence, the inventor of spectacles. God forgive him his sins. Died in the year of our Lord 1317." Armati is credited with the discovery of glasses in 1285. The American Encyclopedia of Ophthalmology, 7:4898, thus summarizes the history of lenses: "The inventor of glasses is unknown; the nations of antiquity probably knew nothing of these instruments. . . . Near the end of the thirteenth century convex-spherical lenses came into use in China and in Europe. It is probable that neither obtained their knowledge directly from the other." The earliest known pairs of spectacles consisting of two large circular lenses, connected by a nose-bridge, known to have been the property of the Renaissance humanist Willibald Pirckheimer (1470-1530), are on exhibition in Nuremberg museum.

AMERICAN CONFERENCE ON HOSPITAL SERVICE

The first regular meeting of the American Hospital Conference, which was organized in Chicago, April 21, 1919,¹ for the purpose of establishing a closer affiliation of all organizations interested in the betterment of hospital service, was held at Cincinnati, September 9-12, in connection with the annual meeting of the American Hospital Association. A constitution and by-laws were adopted in which the name of the organization was changed from the American Hospital Conference to the American Conference on Hospital Service. The organization is composed of two accredited delegates from each of the following fifteen organizations:

- American Association of Industrial Physicians and Surgeons.
- American Association of Hospital Social Service Workers.
- American College of Surgeons.
- American Hospital Association.
- American Medical Association.
- American Nurses Association.
- Association of American Medical Colleges.
- Catholic Hospital Association of the United States and Canada.
- Federation of State Medical Boards of the United States.
- International Compensation Board.
- Medical Department of the United States Army.
- Medical Department of the United States Navy.
- National League of Nursing Education.
- National Organization for Public Health Nursing.
- United States Public Health Service.

Provision is also made for the appointment of honorary delegates who have the privilege of the floor and may serve on committees but are not entitled to vote or to hold office. The organization will be controlled by a board of eleven trustees, including the president and treasurer; the other nine were elected for terms of one, two and three years so that three vacancies will occur each year.

The office of president and that of executive secretary for the present have been left vacant, the trustees being empowered to fill these positions from the best talent available. In the election of officers, Dr. A. R. Warner, superintendent of Lakeside Hospital, Cleveland, was made first vice president;

¹ See Report of the Council on Medical Education, J. A. M. A. 72:1757 (June 14) 1919.

Miss Clara D. Noyes, president of the American Nurses' Association, second vice president, and Dr. Harry E. Mock, president of the American Association of Industrial Physicians and Surgeons, was elected treasurer. Nine trustees were elected, three each for terms, respectively, of three years, two years and one year. Those for the three year term were Dr. S. S. Goldwater, director of Mount Sinai Hospital, New York; Dr. John M. Dodson, dean of Rush Medical College, Chicago; and Mr. John G. Bowman, director of the American College of Surgeons, Chicago. For the two year term those elected were Father Charles B. Moulmier, president of the Catholic Hospital Association, Milwaukee; Miss Edna G. Henry, president of the American Association of Hospital Social Workers, Indianapolis, and Dr. Roger Morris, professor of medicine at the University of Cincinnati. For the one year term those elected were Col. James D. Glennan of the Medical Department of the United States Army; Senior Surgeon J. H. White of the United States Public Health Service, and Dr. David A. Strickler, president of the Federation of State Medical Boards of the United States, Denver. The next meeting will be held in Chicago during the first week in March following the Sixteenth Annual Conference of the Council on Medical Education.

Delaware June Examination

Dr. H. W. Briggs, secretary of the Delaware State Board of Medical Examiners, reports the written and practical examination held at Wilmington, June 17-19, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 10 candidates examined, 9 passed and 1 failed. Six candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	P-r Cent.
University of Maryland	(1919)	76.8	
University of Nebraska	(1919)	82.3	87.3
New York Homeo. Med. Coll. and Flower Hosp.	(1918)	88.6	
Jefferson Medical College	(1919)	86.6	
Medico-Chirurgical College of Philadelphia	(1915)	89	
University of Pennsylvania	(1917)	84.8	80.8
University of Virginia	(1918)	81.3	
Temple University	(1918)	71.8	
College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Jefferson Medical College	(1912)	Pennsylvania	(1913) Vermont
Medico-Chirurgical Coll. of Philadelphia	(1901)	(1913)	Penn.
University of Pennsylvania	(1915)	(1918)	New York

Michigan June Examination

Dr. B. D. Harrison, secretary of the Michigan State Board of Registration in Medicine, reports the written examination held at Ann Arbor, June 10-12, 1919. The examination covered 14 subjects and included 100 questions. An average of 75 per cent. was required to pass. Twelve candidates were examined, all of whom passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
University of Michigan Homeopathic Medical School	(1896)		82.3.
(1917)	84.6, 84.6, 85, 86.4, 86.9, 87, 87.5, 94.7		
University of Michigan Medical School	(1918)	83.6, (1919)	85.9
University of Pennsylvania	(1919)		82.9

Vermont June Examination

Dr. W. Scott Kay, secretary of the Vermont State Board of Medical Registration, reports the written and practical examination held at Burlington, June 26-28, 1919. The examination covered 12 subjects and included 90 questions. An average of 75 per cent. was required to pass. Nineteen candidates were examined, all of whom passed. One candidate was licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Lovola University, Chicago	(1918)	80.8	
University of Vermont	(1915) 87.8, (1918) 84.2, (1919) 79.8,	80.3, 81.9, 82.2, 85, 85.1, 85.3, 85.5, 86, 86.2, 86.4, 86.8, 86.6, 88.1, 89, 90.1,	
College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Baltimore Medical College	(1906)	New Hamp.	

Book Notices

TRAINING SCHOOL METHODS FOR INSTITUTIONAL NURSES. By Charlotte A. Atkins. Cloth. Price, \$2.25 net. Pp. 337, with illustrations. Philadelphia: W. B. Saunders Company, 1919.

This book especially emphasizes the importance of common sense methods, and of golden rule standards in the management of schools for nurses. The first section of the book takes up the task of the training school, the pupil, the teacher, the course of study, principles and methods of teaching. While not minimizing the importance of proper educational standards, it points out the danger of losing sight of service to the sick in the ever increasing demands of the training school curriculum. Good moral character, intelligence and broad human sympathy are primary requisites in the candidate for training. The author urges the importance of clear, definite, painstaking, practical instruction at the very beginning of the course. She considers the junior year the time of greatest importance in the life of the student—the time when methods of study, of thought and of work are being formulated; the time when new ideals and visions of service should inspire to lives of usefulness. The choice of teachers and methods of teaching are treated in a very helpful and suggestive manner. The second section of the book deals with the head nurse, her duties and responsibilities, and her relation to the patient, to his relatives, to the student nurse, to the staff and to the institution. Bedside teaching, ward housekeeping, general management, records and orders are all carefully and systematically treated. One chapter each is devoted to the duties and responsibilities of the chief surgical nurse and to the night supervisor. To the instructor of nurses, to the head nurse or supervisor of nurses the author brings much of inspiration as well as a broad fund of knowledge gained from many years of experience as a teacher of nurses and as a hospital executive.

FIRST LESSONS IN BACTERIOLOGY FOR NURSES. By M. E. Morse, M.D., Pathologist to the Boston State Hospital. Cloth. Price, \$1.25 net. Pp. 139, with 30 illustrations. Philadelphia: W. B. Saunders Company, 1919.

This is a practical discussion of one of the most important of the branches of medicine of which the nurse should have a clear understanding. Having a practical knowledge of bacteriology, she is able to understand why she does certain things and the importance of doing them well. The author has succeeded in avoiding unnecessarily technical language and in presenting the subject in such elementary terms as to make it possible for the average nurse to get a good fundamental knowledge of what bacteria are, how they grow and what they do. Separate chapters are devoted to the bacteriology of special diseases, as tuberculosis, pneumonia, typhoid fever, measles, scarlet fever, whooping cough and venereal diseases. In separate chapters are discussed immunity, vaccines, serums, etc. While elementary and written especially for nurses, physicians who realize that they are becoming "rusty" will find this little book helpful as a first step in "brushing up."

CLINICAL CASE TAKING: AN INTRODUCTION OF ELEMENTARY CLINICAL MEDICINE. By Robert D. Kohn, M.A., M.D., Consulting Physician, Tan Tock Seng Hospital, Singapore. Cloth. Price, \$1.50 net. Pp. 104. New York: Paul R. Hoeber, 1919.

This is a little volume of about ninety pages. While intended primarily as a guide for students in the taking of case histories, it is in effect a small compend of physical diagnosis, and as such fulfils its purpose admirably. The student is taught how to take complete histories, special attention being paid to the present complaint, the technique of examination, and to a certain extent how to interpret the results. A few of the commonly used laboratory methods are also given. We believe that the technique of taking diastolic pressure should be included, and that attention should be drawn to the value of the pulmonary excursion. The intern just entering on his medical service, and the student, should alike profit by the valuable suggestions made by the author.

Social Medicine, Medical Economics and Miscellany

EFFECT OF THE HIGH COST OF LIVING ON PUBLIC HEALTH

The effect of the high cost of living on health was investigated by the department of health of the city of New York (Harris, L. L.: Some Medical Aspects of the High Cost of Living, *Am. J. Pub. Health* 9:491 [July] 1919) just prior to the outbreak of the epidemic of influenza in 1918. What foods working people do without when prices are high, how many women and children are forced into labor by the high cost of living, and how much their nutrition is reduced were queries to which the investigation sought answers. It was instituted on the assumption that "an adequate income plays a greater role in the maintenance of public health than any other single factor." Public health nurses gathered detailed information relative to 2,084 families, representing, in income and nationality, a typical cross-section of the population of New York. Twenty-one per cent. had a total annual income of \$600 or less; 51 per cent., of \$900 or less, half that declared necessary for a family of five by the U. S. Commission of Labor, in 1918. In 9.8 per cent. of the homes, the housewife had been compelled to enter industry; 9.1 had had, for the first time, to seek charitable aid. It was found that as effects of the low economic status boarders are taken in, overcrowding the homes; fatigued mothers are prevented from giving proper maternal and nursing care to the children and the sick members of the family, on their return, at night, from a day's arduous labor; illness is augmented, because special treatment, nursing care, and freedom from work and worry cannot be had, and recovery is retarded for the same reasons, and because essential, nourishing foods are unobtainable. A delayed recovery results in an added loss of time from work, and, therefore, in a progressive increase of bad conditions. The high cost of living forced a large proportion of families to dispense with such foods as meat, eggs, butter, milk and sugar, foods of a class particularly needed in the treatment of such diseases as tuberculosis. The condition bore heavily on children. In 296 families, milk was entirely eliminated from the children's dietary, and, in seventy-one, very considerably reduced. Butter was eliminated in 370 and reduced in 191; meat, eliminated in 544 and reduced in 238. Much more marked eliminations and reductions of these nourishing foods were practiced among the adult members of the families. In 628 families, the high cost of living had a pronounced effect on the quality and the amount of clothing which they were able to purchase, and, in 507, accustomed forms of recreation had been largely dispensed with. In 287 cases, the high cost of living retarded recovery from illness, and cost a loss of working time, valued at \$41,395, in 285. "The industrial worker," it is concluded in the report, "should receive adequate wages in proportion to the cost of the necessities of life, lacking which, not charity but a pension from the community in whose behalf he has labored" should be given.

VENEREAL DISEASE PROPHYLAXIS

Early in 1919, an interdepartmental committee was appointed in Great Britain to consider what measures should be taken to mitigate the dangers of the dissemination of tropical and other diseases among the civil population during the demobilization of troops. A note on prophylaxis against venereal diseases has just been issued in the form of a report to the minister of health. In analyzing this report the *British Chemist and Druggist* says: "A good many witnesses appear to have been examined and various statistics were before the committee as to the effect of prophylaxis after exposure to venereal diseases. In regard to the general experience of prophylactics distributed before exposure to infection, as prevailing in the various services, the committee came to the conclusion (1) that certain drugs, if properly applied, are efficacious in preventing venereal disease; (2) that

if these drugs are not properly or skillfully applied their efficacy cannot be relied on; (3) that the issue of prophylactic 'packets' tend to give rise to a false sense of security, and thus to encourage the taking of risks which would not be otherwise incurred and the neglect of facilities for early treatment when available, and in certain cases might even increase the spread of disease; (4) that, in spite of the most careful instruction, the grant or issue of 'packets' results in many an individual using them for self-treatment after he finds himself infected; (5) that, where preventive treatment is provided by a skilled attendant after exposure to infection, the results are better than when the same measures are taken by the individual affected, even after the most careful instruction; (6) that the excessive consumption of alcoholic liquors not only diminishes the sense of responsibility, but also tends to prevent the proper use of prophylactics and to delay the individual's application for skilled treatment; (7) that the most carefully organized 'packet' system, such as exists now in the army (a system which would be unattainable in the civil community), has not produced such a general reduction in the incidence of venereal disease as to counteract the disadvantages mentioned in these conclusions; (8) that the organization of recreation and social amenities has assisted in the reduction of the incidence of venereal diseases in the services before the war, and has also assisted in preventing that increase in the incidence of these diseases which, from past experience, might have been anticipated during the war; and (9) that energy should not be dissipated on measures of doubtful value, but concentrated rather on wise propaganda and the provision of early, prompt and skilled treatment, in order to diminish the prevalence of these diseases. It should be recognized that failure to cure these diseases is one of the main causes of their prevalence, and that failure to cure, in the most skilled hands, results largely from failure to treat them in their early stages. The general conclusion is that there has not been sufficient evidence of the beneficial results gained by the distribution of prophylactic packets to prove the value of the system or to justify recommending its official encouragement among the civil population."

SANITATION IN THE TROPICS

When the term "tropical sanitation" is used in this country, one is likely to think of the work accomplished by army medical officers in Havana, the Canal Zone, Porto Rico, etc. A very different picture of the problems which Latin American countries have to face in their efforts to improve sanitary conditions, is given in the book which the veteran medical journalist of Peru, Dr. C. E. Paz Soldán, has recently published (*Las Bases médico-sociales de la legislación sanitaria del Perú*, Biblioteca de la Reforma Médica, Lima, 1918). Dr. Paz Soldán reviews the progress of sanitary legislation in his country from the colonial times when plagues were considered punishments inflicted by Providence, and public prayers the only weapons with which the people defended themselves. The picture he outlines of present sanitary conditions is rather lugubrious. In his opinion the most difficult handicap in Peru is that due to race distribution. In contrast with Argentina, Uruguay and Brazil, which have a relatively large population belonging to the Caucasian race, Peru has in its territory a larger percentage of Indians than any other South American nation, forming four fifths of the whole population. In addition, other non-Caucasian elements have been added, among them being the African negro and more recently Chinese and the Japanese. On the Spanish element, which is the basic element of the white population, there have been superimposed of late Italians, Englishmen, Frenchmen, Slavs and Turks. In spite of immigration, however, a decrease of population has been taking place to such an extreme that in the author's opinion Peru is a country without people. In addition to ethnical considerations, physical conditions complicate the situation, since the great mountain range of the Andes divides the country into three different sections, each one of which has entirely different problems. Acute as the public health problem is in the rural sections where people live in inadequate dwellings under

insanitary conditions, it is just as pressing in Peruvian towns, which in general and with one possible exception, Lima, lack safe water supplies and modern systems of garbage and sewage disposal. The descriptions of the way people are lodged are depressing, indeed. As typical of conditions in one of the ports with the largest commerce, he quotes from a city physician's report the following :

In small rooms built of dirt, dung and straw; under roofs covered with reeds and dirt; with few if any windows, you will find the worst possible congestion of all kinds of people and animals: dogs of all breeds, rabbits, chickens, ducks and the never to be missed dockery with its old and odorous equipment which the family use for bedclothes.

As can be expected, all sorts of epidemic diseases prevail in Peru. While no exact figures are available since the sanitary services are not organized, it is known that smallpox never ceases its ravages, especially in the interior of the country. Tuberculosis is present all over the country, receiving each year new impulse from the discharge of tuberculous soldiers from the army. Next to smallpox, which is estimated to cause from 15,000 to 20,000 deaths annually, typhus fever is probably the most serious disease, causing annually thousands of deaths, especially among the Indians of the *pinos*. But likewise plague, leprosy, typhoid, hookworm, malaria and practically every other tropical disease is undermining the national vitality. In concluding, Dr. Paz Soldán says that probably all these evils are the work of the past; and at this moment when humanity is looking toward the future, it may be expected that the dawn of a new epoch is about to appear. The first step in the new road to be traveled must, of course, consist in the enactment of adequate sanitary legislation, and it is on this point that the author insists in his timely essay.

ANOTHER DECISION ON THE HARRISON LAW

The commissioner of internal revenue, July 12, issued a decision based on the United States circuit court of appeals in the case of *Thompson v. the United States*, which came up on a writ of error from the United States district court for eastern Missouri. The court held that the Harrison law, being a revenue measure, is not an unconstitutional invasion of the police power reserved to the states. Regarding expert testimony by physicians as to the manner of treating drug addicts, the court held it proper to permit physicians to testify as experts as to well recognized methods of treating drug addicts, to show that the dispensing of narcotics, in the case in question, was not done in a legitimate manner. The expert testimony in this case was that, unless confined so that he cannot secure a supply of drugs secretly a drug addict cannot be cured. The court held that this testimony was properly admitted. The court further held that although enacted under the taxing power of Congress, it is to prevent the growing use of narcotics, which Congress regarded as a menace to the nation, and that the act has a moral end as well as being a revenue measure.

In regard to the sale of drugs by physicians, the court held that the exemption of a physician "in the course of his professional practice only" from the requirement that narcotics shall be dispensed on an official order form does not justify a physician in selling narcotics if he does not do so in good faith for the purpose of securing the relief of one suffering from an illness or to cure him from the morphin habit. The exception in the law must be construed strictly, and those who claim the benefit of any such exception must establish it as being clearly within the words as well as within the reason thereof. This means that the burden of proof of good faith lies on the physician accused of violating the law. The court also holds that in cases in which physicians furnish narcotics to addicts in decreasing quantities and claim to be curing the addict, the physician must be in personal attendance or must give the addict such personal attention as is sufficient to show that he is acting in good faith. The evidence showed that the defendant in this case was sending drug addicts morphin by mail or express without personal attendance on them, reducing the amount slightly with each succeeding shipment. The court held these reduc-

tions to be evident subterfuges for the purpose of evading the law and that the defendant under the cloak of a practicing physician was selling narcotics not in the regular practice of his profession.

This decision confirms the constitutionality of the Harrison law, which has already been upheld in a number of similar decisions. It emphasizes the moral justification for the law and holds that a law can have at the same time both a moral and a practical justification. It affirms the value of expert testimony in deciding what are proper methods of treating drug addiction, and it further holds that personal attendance on the part of a physician is a necessary part of such treatment.

DEPORTATION OF WOMEN WITH VENEREAL DISEASE

According to an item published in the *Star and Herald* of the Republic of Panama, under a decree issued by the government of the republic, 124 women are to be deported from Panama. The law under which this decree was issued, provides for the deportation of all those characters, or persons of ill-fame resident in the republic, irrespective of nationality. The government of the republic has considered that the best means to keep the cities and towns moral is to deport these women to their native countries. Of the 124 women to be deported, 84 were from the island of Jamaica, 7 from the island of Barbados, 2 from the island of St. Lucia, 5 from the island of Trinidad, 19 from the island of Martinique, 5 from the island of St. Thomas, and 2 from the island of Porto Rico.

Medicolegal

Leaving Packing Without Notifying Patient

(*Studyer v. Wagon Owner*, 171 N. W. R. 15)

The Supreme Court of Iowa, in affirming the order of the trial court, as having properly directed a verdict for the defendant at the close of the plaintiff's evidence, says that the plaintiff was in a hospital in care of the defendant as a surgeon for a period of five days. He performed a surgical operation on her consisting in lancing of urethral abscess. It was located on the urethra and on the vagina wall. At the time of the operation the defendant used a piece of cheesecloth or surgeon's gauze for the purpose of absorbing blood and pus from the incision. This was placed as a packing within the vagina. The particular piece used by the defendant was described by the plaintiff's husband as a witness as being 2 feet long and 2½ inches wide. Ten weeks after the discharge of the plaintiff from the hospital she discovered a smaller piece of cloth or gauze within the vagina and removed it. The ultimate complaint of her pleading was that the defendant failed to advise her that he had inserted any cloth or gauze in the vagina, and that she was thereby prevented from discovering its presence, and that its long continuance therein resulted in injury to her. Her experts testified that the use of gauze or cloth was proper, and that its long continuance without change was not necessarily injurious, though very offensive. At the expiration of five days the plaintiff left the city, and accepted no further attention from the defendant. Up to that point of time the presence of the packing in the vagina was neither injurious to the plaintiff nor wrongful on the part of the defendant. If the plaintiff did not know of its presence, her husband did. Its removal called for no surgical skill. Moreover, it might well be assumed that during her further convalescence she would seek the aid of a local physician, and the presence of the packing would be readily discovered by any physician.

Assuming, however, for the sake of the argument, that the defendant should have warned the plaintiff and should have instructed her as to the removal of the packing, and that he failed in his duty in such respect, yet the evidence wholly failed to show that the presence of the packing resulted in any injury to her. At the time of the operation and for some

time prior thereto, the plaintiff was suffering from a serious disease. One of the resulting effects of such disease was the abscess for which she obtained surgical relief. The surgical operation was not calculated to check the disease. The defendant did not treat her for such disease. The symptoms suffered by the plaintiff after the surgical operation were of the same kind as those suffered before the operation, though they grew more severe with the progress of the disease. Two expert witnesses testified on behalf of the plaintiff that the presence of the packing for such inordinate length of time could produce septicemia, especially in view of its contact with a surgical wound. But they testified also that even this was improbable. It appeared affirmatively and without dispute that the surgical wound "healed all right," and that it was involved in no complication whatever. There was no evidence, expert or otherwise, that the plaintiff had suffered from septicemia. On the entire record the court is satisfied that no cause of action was disclosed against the defendant.

Cold Storage Limitation to Protect Public Health

(*Nolan v. Jones et al. (Pa.)*, 106 Atl. R. 235)

The Supreme Court of Pennsylvania holds constitutional the statute of that state, of 1913, entitled "An act for the protection of the public health and the prevention of fraud and deception, by regulating the storage and sale of cold-storage foods," etc., so far as it limits the time within which foods, particularly butter, may be held in cold storage, and then sold or offered for sale, as that no butter which is held in cold storage for a longer period than nine months shall be sold, offered or exposed for sale. The court says that no part of the federal constitution, or any of the amendments thereto, takes from the states the right to determine what shall be prohibited as prejudicial to the public good; and the fact that, under the peculiar circumstances

of any given case, the particular article condemned happens to be "wholesome" cannot affect the application of a legitimate police statute comprehending a whole class of objects, of which the kind in question is one, the class being such as reasonably justifies regulation for the preservation of the public health. It is a matter of common knowledge that food will start to decay even in cold storage, and many articles, when subjected to a long period of such treatment, although able successfully to withstand inspection immediately before removal, will thereafter rapidly putrefy or deteriorate; hence it cannot be held that any measure beyond enforced inspection is unreasonable. Ordinarily it is for the legislature to determine whether inspection or prohibition is the appropriate remedy, and there is nothing about the present statute which would justify the court either in determining that the inhibition under attack is an unreasonable exercise of police power or in assuming that the law was enacted otherwise than in good faith and for the public welfare. In Pennsylvania only the special legislation that is expressly forbidden in Section 7, Article 3, of the state constitution is invalid on that particular ground, and there is no prohibition to be found therein against special food laws; furthermore, cold storage food is now so universally used that it has, even in popular acceptance, fallen into a class by itself, which requires legislative regulation for "the protection of the public health." This is not undue, but just and proper, class legislation; and, because an act such as the present of necessity fails to govern articles not placed in cold storage, that act does not, in any legal sense, make the statute one granting special "privileges and immunities" to the owners of the latter class of food; or, to put it more concretely, if it were conceivable that butter could be preserved in salable condition for more than nine months without modern, scientific cold storage, and hence that owners thereof would be privileged to dispose of their property, on the market, under circumstances which would deprive owners of cold storage butter from so doing, that would not make the legislation before the court subject to the charge of granting exclusive privileges and immunities to a special class. The statute is general in that it applies to a distinct and justifiable class, and all persons dealing in food articles, at their option, may or may not bring themselves within the statute.

Leukocyte Counts During Influenza.—Leukocyte counts were made by Montgomery and Dunham in thirty cases of influenza occurring in infants and children less than 12 years of age. They found that the tendency in uncomplicated influenza in infants and children is toward a leukopenia, rather than a leukocytosis. There is a tendency to a slight leukocytosis in complicating pneumonia. In this series, in all pneumonia cases resulting fatally, the leukocyte counts were under 10,000. The prognosis, in general, is better in pneumonia cases which exhibit a leukocytosis. Differential counts have shown: (a) a tremendous variation in the differential formula, and (b) nothing sufficiently constant to be of clinical aid in diagnosis or prognosis.

Fat Metabolism of Infants. The observations recorded by Holt and others indicate that corn oil and nut butter, the vegetable fats studied, are valuable foods for children, are exceedingly well borne and are apparently digested and absorbed with ease. The authors, therefore, feel warranted in the belief that these articles may safely be introduced into the regular diet of children, and that to a considerable degree they may be substituted for the more expensive milk fat, given either as milk or as butter, but they should never entirely replace milk fat. How much milk fat is needed to furnish the amount of the fat-soluble vitamin required for normal growth and nutrition has not yet been determined by the authors.

Cerebral Involvement in Hereditary Syphilis.—According to a survey of the literature by Jeans there is found involvement of the central nervous system, as shown by the cerebrospinal fluid, in about one third of all individuals with acquired syphilis. Among the 214 patients having hereditary syphilis

who were studied by Jeans, a similar incidence of involvement of the central nervous system was found.

Rheumatic Nodules.—According to Brennemann all observers are agreed on two points, practically: the rheumatic nodule means rheumatism and it practically always means endocarditis. These nodules vary in number from one or two to 160 or more—commonly there are eight or ten. If numerous, they are always widely scattered. The greater the number the more surely will some of them be very large, especially over the patellas, the back of the head, or on the spines of the vertebrae. They occur always in connection with the deep fascia, the tendons, or the periosteum, but they have favorite localizations. Thus they are nearly always found, if present at all, about the condyles of the humerus, and in and about the olecranon process. Occasionally, a very large one is found near the end of the olecranon process that is almost indistinguishable till it is found to be movable. It is especially about the elbow that the joint must be flexed properly, and careful search made both with the eye and the finger. They are rarely as large here, except over the olecranon, as they are in other locations where they are connected with the periosteum. In Brennemann's experience they occur relatively frequently and are very large, not only the margins as commonly reported, but over nearly the whole of the patella, commonly on both knees. When the knee is flexed sharply they are very conspicuous. They are frequently found over the malleoli, especially over the external malleolus, on the styloid processes of the radius and of the ulna, but they are never large or numerous here. A striking and not uncommon location is on the knuckles and sometimes the tendon of nearly every knuckle is the seat of from one to five nodules. If the hand is open they quite escape notice; if the hand is tightly clenched they appear as prominent, shining, whitish or grayish clusters along the tendons. Less frequently they occur on the toes. In six or eight cases the most prominent nodules have been under the scalp, always on the back of the head. If present, there are usually from two to six, or more, large bumps nearly the size of a hazel nut. Occasionally they show a distinct predilection for the spine, where they may be hard to find if laterally or deeply seated, and most conspicuous if located on the tips of the spinous processes. Occasionally they occur along the spines and vertebral borders of the scapulae, less frequently about the shoulder joint and along the crests and articulations of the ilia. Rheumatic nodules have a tendency to appear in groups, or waves. The life of the individual nodule varies from a few days to as many months.

Cerebral Complications in Mumps.—Casparis records two cases. In one the disease was ushered in by delirium and vomiting and in the other by headache with tache cerebrale.

Diabetes Insipidus.—With a view to determining whether endocrinal involvement was present in Cowie's case, roentgenographic examination of the sella turcica was made, and epinephrin and glucose blood sugar curves were studied, but the result was negative, hence Cowie concludes that the case was idiopathic in origin.

Toxic Properties of Milk.—Milk heated to 80 or 85 C. for from twenty to thirty minutes and kept at 37 C. decomposes with the elaboration of definite poisonous substances, a fact which, Ford says, should be kept clearly in mind in the consideration of the problem of milk pasteurization; and, under all circumstances, milk heated to temperatures sufficient to destroy vegetative bacteria but not their spores should be kept at a low temperature to prevent the development of these spores and should be used within a brief interval after the heating. Whether the bacterial products found in this decomposed milk have any poisonous action when taken into the digestive tract has not been determined, but in view of their presence in milk the practice of keeping pasteurized milk for any considerable period of time before using is condemned strongly by the authors. Finally, the occurrence of toxic substances in heated milk arising from the development of spore bearing bacteria requires a rigid supervision of milk production before pasteurization to prevent the entrance of organisms of this character.

*Undoubted Pandemic Disease (Influenza?). D. Roberts, New York, U. S. Army.—p. 377.
Pneumonia as a Complication of Epidemic Influenza. A. V. Bock and J. L. Stoddard, Boston.—p. 407.

Food Factors in Gastro-Enterology.—Mendel emphasizes the fact that dietetics offers no cure-alls to the gastroenterologist, nor does any other mode of therapy. Calories, proteins, vitamins, acidophilic bacteria, merely furnish viewpoints from which important problems of practice may be examined.

Diagnosis of Late Syphilis of Central Nervous System.—Inasmuch as lumbar puncture is practically without danger, and as it opens up a means of diagnosing late syphilis of the central nervous system when other diagnostic means fail, and as late syphilis of the central nervous system calls for a special form of treatment, Frothingham believes it fair to demand that in all cases of old syphilis a lumbar puncture should be performed as a diagnostic procedure before instituting treatment.

Spinal Decompression.—The value of operation for cranial decompression, especially that of subtemporal decompression in supratentorial lesions, has been well recognized for years, Sharpe maintains that laminectomy for spinal decompressions or for exploration is of equal if not greater value. It has in the past been employed but rarely, and then usually at the wrong time, and as a last resort when all other measures have failed and the nerve tissue is irreparably damaged. And yet there can be no doubt that in patients having obscure lesions of the cord or in doubtful diagnoses an exploratory laminectomy, frequently terminating as a simple decompression, has been followed by remarkable improvement of the patient. The spinal operation has an advantage over the cranial decompression, for while a cranial decompression may be used for an exploratory procedure, the lesion itself can rarely be removed through the original incision; so that a second operation, the formation of an osteoplastic flap, is frequently necessary. But in spinal laminectomy the major part of the cord at the supposed site of the lesion is before the eye of the operator for exploration, and spinal decompression, exploration and possible removal of a lesion can be carried out at the one operation. Furthermore, diagnosis and localization of cord lesions is more accurate than the lesions of the brain. Sharpe discusses the value of exploratory laminectomy in cases of doubtful diagnosis or lesions of obscure origin which can be localized, and the value of spinal decompression in certain selected cases of well recognized forms of cord disease which formerly were not considered amenable to surgical interference.

Localization of Tumor Metastases.—Armstrong and Oertel claim that the localization of metastases depends on a number of factors. Important among these are: 1. The quantity of the tumor elements and the methods of dissemination. 2. Effects of injurious metabolic products of tumor cells on a tissue, causing degeneration and inflammation and thereby weakening its physiological resistance. 3. Close biogenetic (embryonic) relation of tumor cells to a tissue soil, whereby types of tumor cells derived from an embryonic layer grow

more readily in the environment of organs or tissues which are derived from the same layer of the blastoderm.

Unidentified Pandemic Disease.—Intravenous injections of a mixed influenza vaccine, given in doses sufficiently large to cause a definite reaction consisting of a chill or definite chilly sensation one-half hour after the injection, accompanied by a rise in pulse rate and sometimes by a slight fall in temperature, Roberts believes to have been the best form of treatment used in several hundred of these cases. In a consecutive series of 200 cases of definite influenza pneumonia treated by his plan the mortality was 9.6 per cent. This was in striking contrast to a series of eighty-six consecutive cases treated by an expectant plan with a mortality of 3.13 per cent. By this plan of treatment not all cases can be saved, but Roberts was convinced that in many cases which were naturally terminated fatally the patient recovered promptly in the most striking manner.

*Result of Examination of Prostate and Vesicles in 125 Cases with Negative Venereal History. G. G. Smith, Boston, and H. N. Klein, U. S. Army.—p. 300.

Examination of Prostate and Vesicles in 125 Cases with Negative Venereal History.—Including all the cases noted in their records as having had no venereal disease, Smith and Klein found that sixteen cases out of 125 showed more than two pus cells per oil immersion field and night, therefore, he said to have prostatitis or vesiculitis. Cases with indurated vesicles but with no pus in the secretion were not included. In this series of 125 cases, therefore, about 13 per cent. of the men who had no venereal disease, showed definite signs of a prostatitis or vesiculitis. In practically all of these there were no symptoms referable to the prostatic condition, nor did it seem, in any of these cases, as if their arthritis was due to infection from this source.

Oxygen of Blood in Pneumonia.—The results of a study of thirty-three cases of pneumonia in which the oxygen of both arterial and venous blood were determined are given by Stadie. The Rockefeller Institute arterial puncture was done six times on one patient without injury. In all, about ninety punctures were made and no ill results have been observed. In five normal subjects the mean arterial unsaturation was 5 per cent. of the total oxygen capacity; the mean venous unsaturation was 26.8 per cent. In the pneumonia cases the arterial oxygen unsaturation varied from 0.0 to 68.2 per cent.; the venous oxygen unsaturation varied from 14.4 to 85.5 per cent. In the fatal cases, as opposed to the nonfatal cases of pneumonia, the mean arterial oxygen unsaturation was 32 per cent. as against 13.9 per cent. As a rule, an arterial unsaturation of over 20 per cent. was associated with a fatal outcome. Similarly, the mean venous oxygen unsaturation was 57 per cent. in the fatal cases and 36.3 per cent. in the nonfatal cases. In five cases in which no cyanosis was observed at any time, the mean arterial oxygen unsaturation was 5.4 per cent. the mean venous oxygen unsaturation 31.5 per cent. In cases which showed cyanosis of varying degree during the course of the illness, the mean arterial unsaturation was 24.7 per cent., and the mean venous unsaturation 44.5 per cent. Cases without cyanosis have an arterial unsaturation close to the normal. There is a definite relation between the degree of cyanosis and the percentage of arterial unsaturation. With increasing cyanosis the arterial unsaturation becomes greater. The venous unsaturation varies similarly. In individual cases with marked cyanosis, associated with high arterial unsaturation, the clinical improvement of the patient and the diminution of the cyanosis were accompanied by a similar diminution in the arterial and venous unsaturation. Conversely, an increase of cyanosis was accompanied by an increase in arterial unsaturation. It is evident to Stadie that the cyanosis of pneumonia patients is due to the incomplete saturation of venous blood with oxygen in the lungs, and that the various shades of blue observed in the distal parts are caused by an admixture of reduced hemoglobin and oxyhemoglobin in the superficial capillaries. No unusually low total oxygen capacities were observed, even in fatal cases with intense cyanosis. On the contrary, in these cases the total oxygen capacity was unusually high, pointing toward a concentration of the blood. Again, in only one case was there any marked fall in the oxygen capacity during the illness. Therefore, methemoglobin formation, in these cases, can hardly have occurred to such an extent as to be an important factor in the production of cyanosis. Of the thirty-three cases studied, however, only seven were lobar pneumonia cases, the rest being of types ordinarily unusual and which have accompanied the recent influenza epidemic; and of the seven, not all were in all respects typically lobar. The possibility still remains, therefore, that in typical lobar pneumonia caused by the pneumococcus, methemoglobin may play a part in the cyanosis.

Blood Gases in Anemia and Heart Disease.—The data presented by Harrop indicate that at least in many circulatory diseases during decompensation, particularly when there are physical signs of pulmonary congestion, there is a disturbance of the pulmonary exchange, as indicated by the lowering of the percentage saturation of the arterial blood with oxygen. The oxygen consumption tended to be high in individuals with cardiac disease during the periods of marked decompensation and lower as compensation was regained.

Causes of Cyanosis.—The data presented by Lundsgaard in these two papers are said to prove that abnormally high oxygen unsaturation of the blood is a cause of cyanosis. This increased oxygen unsaturation may be produced in two ways: (a) by an increased reduction of oxyhemoglobin to reduced hemoglobin in the peripheral capillaries, and (b) by an incomplete oxidation of the venous blood in the lungs. No

quantitative parallelism exists between the degree of cyanosis and the amount of oxygen unsaturation of the venous blood. The first condition occurs during exercise or when the blood flow is retarded, as in decompensated heart condition. The second condition occurs in certain lung and heart diseases, and when the alveolar oxygen tension is greatly decreased, as at high altitudes. If the blood is completely saturated with oxygen in the lungs, the oxygen unsaturation of the venous blood may increase from thirteen to fourteen volumes per cent., some arterial oxygen unsaturation may be assumed, and the greater this, the lower the venous oxygen unsaturation is. Even if neither rales nor dullness can be detected in the lungs, conditions may exist which prevent complete oxidation of the arterial hemoglobin. This is especially frequent in patients with mitral lesions. Cyanosis cannot be produced in patients whose hemoglobin percentage is below 35 in the Haldane scale (oxygen capacity of 6.5 volumes per cent.).

Erythrosis, or False Cyanosis.—In the venous blood of a patient with Vaquez' disease normal values were found by Lundsgaard for the oxygen unsaturation (reduced hemoglobin), although the total hemoglobin and oxygen capacity were abnormally high. The carbon dioxide content was normal. The color of the skin and mucous membranes was more reddish than blue. Lundsgaard proposes to term this condition erythrosis in order to distinguish it from cyanosis.

*Influence of Alcohol and Nicotin on the Ovary. S. Ogata, Chicago.—p. 123

Reactions to Chilling of Body Surface.—A method and instruments are described by Mudd and Grant by means of which changes in the temperature of the skin and exposed mucous surfaces of human subjects may be followed quantitatively. The method consists essentially in holding in apposition with the surfaces, by means of specially devised "applicator," the terminals of a thermopile in circuit with a d'Arsonval galvanometer. From the thermometer and galvanometer readings the absolute temperature of the surface beneath the thermopile junctions is readily computable at any time. By this thermogalvanometric method the temperature of the skin and oral and pharyngeal membranes was shown to fall with chilling of distant areas of the body surface and to rise again on rewarming the subject. Control experiments showed the blood temperature relatively unaffected by such cutaneous chilling; such small changes as were effected were in the direction of a minute rise with chilling and a fall on rewarming. Two control experiments showed no consequential changes in blood pressure with cutaneous chillings. Animal experiments have resulted in a rise of blood pressure with chilling. An increase in volume of respiratory exchange was found to result from cutaneous chilling. Such respiratory increase usually caused a depression of mucous membrane temperature. Changes in temperature of the skin or exposed mucous surfaces are thus shown to be the result of changes in vasomotor tone in the vessels supplying those surfaces. A fall in superficial temperature indicates vasoconstriction; a rise, vasodilation. Chilling of the body surface causes reflex vasoconstriction in the skin of the head and neck. Earlier attempts at explaining the excitation of pharyngeal and tonsillar infections by cutaneous chilling have been based on the assumption that such chilling causes congestion of the mucous membranes. These experiments show, on the contrary, that chilling of the body surface causes reflex vasoconstriction and ischemia in the mucous membranes of the palate, faucial tonsils, oropharynx and nasopharynx. In four instances exposure was followed by a "cold" or sore throat. The mucous membranes of one subject remained normal after sixteen exposures.

Experimental Cirrhosis of Liver.—In the cases in which Ogata injected alcohol into the portal and mesenteric veins repeatedly there were seen marked cirrhotic changes in the interlobular spaces, with often newly formed bile ducts, especially marked in one case; and in addition in two of the cases there was also a marked round cell infiltration with increase of connective tissue in the central portions of the lobules. Further, he saw also in this series various pronounced degenerative changes of the liver parenchyma. The cirrhosis, however, was not the same as Laennec's cirrhosis of the liver. On the other hand, in the series of cases in which he injected alcohol repeatedly into the ear vein, he observed but slight changes in the interlobular spaces and in the parenchyma of the liver. The difference observed in the two groups of experiments Ogata thinks may be due to the difference in concentration of the alcohol as it arrives in the liver. It is evident that the repeated injections of extract of cigar tobacco into the portal and mesenteric veins may have some toxic effects on the liver. Through the repeated injections of sterilized emulsion of human tubercle bacilli into the portal vein and mesenteric veins of the rabbit, there followed marked changes resembling tuberculous lesions which were followed by an increase of connective tissue, chiefly in the interlobular spaces, together with some toxic effects on the parenchyma of the liver. These experiments seem to indicate, then, that cirrhotic changes in the liver may be produced by killed tubercle bacilli and their toxic products without the presence of any living tubercle bacilli, and that there may be some relation between tuberculosis, especially of the peritoneum and intestine, and cirrhosis of the liver. Sterilized colon bacilli and their toxic products may produce cirrhotic changes in the liver, though not the same as Laennec's cirrhosis.

Influence of Alcohol and Nicotin on Ovary.—Ogata's observations show that the fact that chronic alcoholism of parents has a great influence on their descendants seems to be principally dependent on the injurious influence of the alcohol on the spermatozoon, though in a less degree it may depend on the influence of alcohol on the ovary. There is no apparent influence of nicotin on the ovary.

Micro-Organisms Found in Canned Foods.—Seven hundred and twenty-five cans of merchantable foods in prime condition were carefully examined by Cheyney for bacteria, molds and yeasts. Fifty-eight, or 8 per cent. of these cans, were found to contain living micro-organisms. Not all foods contained them, however, some being found always sterile, some with a constantly low percentage, others with a high percentage of cans containing viable micro-organisms. There was a uniform average found throughout for each food; vegetables being sterile or showing only a small number of cans containing viable organisms (8 per cent.), fruits showing a consistently lower number (3 per cent.), fish and meats varying from 10 to 20 per cent. The micro-organisms isolated constitute a sharply limited group of resistant spore-bearers, including the *B. subtilis-mesentericus* group, the related thermophiles, an anaerobe, four common species each of aspergillus and penicillium, and two borderline yeasts. No pathogenic micro-organisms were found. The bacteria were associated chiefly with the meats, while the molds formed the sole flora of all the fruit cans found to contain living micro-organisms. Thermophiles were found only in crab and lobster. There was evidence to suggest that in certain foods the bacteria and molds had persisted through the processing, and that the usual methods of processing must be increased to obtain actual sterility in these foods.

Compensatory Hypertrophy of Thyroid. From Lusk's experiments the following conclusions are drawn: (1) If in a

pregnant guinea-pig an almost complete extirpation of the thyroid is carried out, pregnancy may continue to take its normal course. Pregnancy does not promote, and perhaps retards in certain cases, compensatory hypertrophy of the thyroid in the mother; and under such conditions hypertrophy of the thyroid in the offspring does not need to take place. There is so far no definite proof that such hypertrophy ever occurs if the thyroid of the mother had previously been extirpated. In the majority of cases, abortion seems to follow an almost complete extirpation of the thyroid of a pregnant guinea-pig. Abortion does not usually interfere with the occurrence of compensatory hypertrophy in the remnants of the thyroid of the mother. In a guinea-pig in which both thyroids have been almost completely extirpated, and subsequently compensatory hypertrophy has taken place, the normal sexual cycle may continue to take place and pregnancy may occur. If one lobe or one lobe and one half is extirpated in a pregnant guinea-pig, pregnancy may proceed. Under those conditions the remaining parts of the thyroid show no deviations from the usual results of these operations. After extirpation of one and one half of the thyroid, a very mild degree of hypertrophy was found in the remaining part.

Streptococci in Sputum of Bronchial Asthmatics.—The different types of streptococci found by Walker and Adkinson in asthmatic sputum are not numerous. Practically all of the hemolytic streptococci were included in the four types, namely, *S. subacidus*, *S. anginosus*, *S. pyogenes* and *S. infrequens*. Practically all of the nonhemolytic streptococci were included in the four types, *S. nonhemolyticus* I, *S. ignatus*, *S. salivarius* and *S. mitis*. In doing the skin tests on bronchial asthmatics, it would seem to be advisable to use the protein of these types of micro-organisms rather than the protein of any one type alone. As a rule, the thick sputum of asthmatics, provided it is washed, contains very few different types of bacteria, and contamination by mouth or air organisms is unusual. For these reasons autogenous sputum vaccines seem to be practical, but they should be made at frequent intervals, since the types of organisms present in sputum are not constant, and therefore there is a chance that some vaccines may not contain the particular organism which is causing symptoms.

Experimental Hydronephrosis—Repair Following Ureterocystostomy in White Rats with Complete Ureteral Obstruction. H. Hinman, San Francisco.—p. 147.

War Nephritis.—The investigation reported on by Keith and Thomson was carried out in thirty-three cases specially selected from about 300. These were all typical cases of war nephritis, and, with one exception, only those were included which from their previous history and clinical condition negatived as far as possible a previous nephritic condition. The authors divide these cases into two groups: Resolving and nonresolving. The resolving group is characterized by (a) rapid disappearance of edema accompanied by a distinct diuresis, copious excretion of chlorides, and fall in blood pressure; (b) rapid diminution in amount of albumin in urine; (c) relatively good renal function. The nonresolving group is characterized by (a) showing disappearance of edema and delayed diuresis; (b) persistent gross hematuria and persistence of albumin in the urine; (c) development of permanent retinal changes; (d) grave impairment of renal function. Relapses are of frequent occurrence in both types of the disease and are of serious prognostic significance. An acidosis of moderate degree is present. In the resolving group this disappears with general improvement, but in the nonresolving group alkali therapy is required to restore the normal acid base relationship. Functional tests are of the greatest value in forming an opinion as to the extent of renal impairment. Prognosis as to ultimate complete recovery, even in the resolving group, must be guarded. In the nonresolving group many cases show relatively early in the disease evidence of permanent renal change. The excretion of alkali is of distinct service in many cases as shown not only by a restoration of the normal acid base relation-

ship in the blood, but also by an improvement in renal function. When death occurs in the first two weeks of the disease an intracapillary glomerulitis is the most striking histologic feature; when death occurs in the fifth week there is found, in addition, a proliferation of the cells lining Bowman's capsule, intense edema of the interstitial tissue, small round celled infiltration and flattening of the epithelium lining the convoluted tubules. When death has been delayed to the seventh week of the disease the proliferated cells of Bowman's capsule are replaced by fibrous tissue, with resulting sclerosis of the malpighian tuft, increase of interstitial tissue, and widespread and severe tubular changes.

Mediastinal Dermoid. A young woman, 19 years old, a native of Russia, complained of difficulty in breathing and weakness. The roentgen-ray examination showed a distinct shadow in the right thoracic cavity. Harris aspirated the mass and withdrew a considerable quantity of semiliquid material, yellow in color. As he withdrew the needle a long hair came out with it, confirming the diagnosis of dermoid

cyst. At operation it was found that the growth occupied almost all of the right pleural cavity and was adherent to the diaphragm, pericardium and tissues about the root of the right lung and other mediastinal structures, and that it had pushed the parietal pleura in front of it as it extended outward into the thoracic cavity. The mass removed was a large cyst measuring 22x19x10 cm. the inner surface of which was covered with hair and the contents consisted of an oily lumpy material and a great deal of long brown hair. Three other small dermoids, 8x1.5 cm., were attached to the main cyst, but did not communicate with it. One about the size of a hen's egg communicated with the cavity of the larger cyst. The weight of this growth was about 2,800 gm. Owing to the fact that the lung which had been compressed by the tumor failed to expand it became necessary later to obliterate the thoracic cavity on that side. The patient then made a complete recovery.

Medicolegal Aspects of Mental Defectiveness.—Discussing the problem of the feeble-minded, Goddard says that we do not protect society by punishing these individuals. Society is never safe when these mental defectives of criminal tendencies or experience are at large. The only protection is to place them in an environment suited to their low mentality. Such an environment is furnished by an institution or colony for the feeble-minded. The courts are largely employed with repeaters. These repeaters are generally mentally defective. That is the logical expectation because mental defectiveness is incurable. An insane person may recover; a mental defective cannot. Once started on a criminal career there is no reforming them because of their weak-mindedness. For the welfare of society and for their own happiness they must be colonized. Present laws make this a slow, difficult and costly procedure.

Frequency of Malaria at Different Ages.—Approximately 50 per cent. of all the malaria in the locality investigated by Bass was found in persons under 20 years of age.

Malaria Without Symptoms.—In 44.91 per cent. of these cases studies by Bass malaria either does not produce any symptoms whatever or at least does not produce symptoms that are recognized as malaria.

Malaria: Dose of Quinin for Children.—Bass states that when the child is less than 1 year of age the proportionate doses for children is $\frac{1}{2}$ that of the adult dose. From 1 year on to 15 years the dose for a child is one tenth the adult dose.

Immunity in Malaria.—Immune bodies are produced in malaria and the immunity processes contribute largely to elimination of the infection. In fact, they are usually sufficient to eliminate the infection in time without the aid of specific medication. In any given locality where malaria is very prevalent, if it were followed by lasting and effective immunity, there should be little malaria in older children and adults. In a locality where approximately 50 per cent. of the community have malaria during a given year, it is observed that malaria occurs about three fourths as frequently in adults as in children. This observation indicates that whatever immunity is produced is not lasting and effective against new infection.

Use of Pepsin Quinin Mixture for Malaria Carriers.—According to Harrington and Barrier the administration of a quinin and pepsin mixture reduces the incidence of unpleasant results about 70 per cent. as compared with the idiosyncrasies manifest following the administration of plain quinin sulphate, without any evidences of impairing the effect on the plasmodia in the circulating blood. After careful investigation, the following proportion of quinin and pepsin was adopted: Quinin sulphate, 90 parts (by weight); milk sugar, 6 parts (by weight); powdered pepsin, U. S. P., 4 parts (by weight). Mix thoroughly and place in capsules No. 0 or No. 3. This mixture gave, in capsule No. 0, 497 grains of quinin sulphate.

Distribution and Destruction of Quinin in Animal Tissues.—Evidence is given by Lipkin bearing on the possibility that there exist in the blood vascular system regions kept almost free from quinin throughout a period of quinin medication. The quinin content of tissues has been more extensively studied. Accumulation at much higher concentration in most tissues than in the blood is confirmed. The suprarenal is prominent in this respect, although not so markedly with intramuscular as with intraperitoneal injections. Fairly large accumulations may occur also in the spleen and kidney; the lymph glands contain much less quinin than the surrounding blood. The liver, kidney, muscle, intestinal wall and probably pancreas, have considerable power to destroy quinin post-mortem, and, therefore, presumably during life. The blood, spleen, suprarenals, bone marrow, lymph nodes, salivary and thyroid glands have little or no such power. The quinin destroying agent extracted from the liver is thermolabile, inactivated at 100 C. and acts best in neutral media. Its action is rapid at first, but soon falls off. It does not act at all in the absence of oxygen, and is hindered by hydrogen peroxid. It can be crudely "purified" by fractional precipitation with alcohol. Quinidin is formed by the action of liver pulp on quinin. Quinidin given to a malarial patient by mouth, in ample doses, was therapeutically inert. As none appeared in the urine, this is probably true also of its metabolites. In the feces of a case of blackwater fever, a brown pigment is described which, although not itself cholecyanin, readily yields this body. New tests for quinin and quinoxin are described. The thallequim test is rendered capable of detecting easily 0.004 mg. of quinin.

Cases of Acute Amebic Dysentery in Asylum Patients Never Out of England. Five hundred and four asylum patients were examined by Smith for intestinal protozoa. Fifty-nine of these had acute dysentery and in three of the cases vegetative *Endamoeba histolytica* were found in the stools. All the usual protozoa were also found in the stools, but the infections were distinctly less numerous than in the patients of another asylum previously examined.

Can Lipoids Act as Antigens?—Wang's experiments showed that in the case of the dry blood an antigenic capacity is found in the extract of a lipoidal nature. This finding differs from that shown in the experiment conducted along similar lines by Ritchie and Miller. The disagreement in the results is probably due to the fact that in the procedure Wang adopted for extraction the blood was treated alternately with ether and chloroform, the extracts derived from both being put together for use. It may also be that, by saponification, the extracts were rendered more easily assimilable in the body of the animal, and, consequently, in a more favorable position to bring on a reaction. With regard to the lipoidal extracts of egg white and horse serum, experiments fail to present any evidence of an antigenic capacity.

Detection of Diphtheria Bacilli in Swabs.—In the examination of swabs for the presence of diphtheria bacilli Wang found that wet serum is a better medium for cultivation. It is, therefore, advisable that the swab instead of being smeared on solidified fluid serum should be put directly if it is received, into the fluid serum and incubated. While a number of organisms met with in the throat are capable of producing acid in the wet serum, this property is especially pronounced in the case of the diphtheria bacillus. This observation would warrant the assertion that, when the reaction of the culture is unchanged or remains plainly alkaline, the diphtheria bacillus may be excluded.

Experimental Scurvy in Monkeys.—Experiments made by Harden and Zilva show that by giving monkeys a good nutritious basal diet, lacking the antiscorbutic factor, scurvy can be induced in these animals. The daily amount of food consumed naturally varied, but on the average the monkey ate about 70 gm. of wheat germ, 100 gm. of boiled rice, 80 gm. of nuts, 80 gm. of bread and 150 c.c. of beer. The autoclaved rice and the wheat germ were made up in a paste with about 100 c.c. of autoclaved milk. The food consumed by the animal was of high caloric value and contained an abundant supply of protein and of the antineuritic factor.

The experiment commenced June 25. The first definite symptoms of scurvy were observed October 18. A second monkey was fed autoclaved rice and bread and milk. The main feature of this diet, in contradistinction to the one of the previous experiment, was that, besides the lack of the antiscorbutic, the antineuritic factor was almost absent. The only source for the antineuritic factor was the autoclaved milk. This animal consumed on the average 200 gm. rice and 40 gm. of bread and half a pint of milk daily. The experiment was started July 28. November 6 decided hemorrhages of the gums were first observed. A third experiment was performed to demonstrate that the scorbutic condition in the monkey induced by dietetic means can be cured by the administration of an antiscorbutic. The main ration of this animal consisted of rice and wheat germ. Bread and monkey nuts were not given to this animal. The average daily consumption was about 200 gm. of rice and 40 gm. of wheat germ. The experiment was started October 18. December 29 slight sponginess of the gums was observed. January 23 the scorbutic condition of the animal was very acute. The antiscorbutic used was lemon juice from which the free citric and other acids had been removed. January 23 the monkey received, by means of the stomach pump, 25 c.c. of the treated lemon juice, which was equivalent in antiscorbutic potency to 100 c.c. of the original juice. The next day it received another dose, equivalent to 100 c.c. of lemon juice. After twenty-four hours an improvement could already be observed. Doses of the treated lemon juice equivalent to 150 c.c., 250 c.c., 250 c.c., and 150 c.c., were administered during the following four days. January 28 the gums were almost normal and the teeth were practically firm. The monkey continued on the scorbutic diet with a daily addendum of treated lemon juice, equivalent to 10 c.c. of the original juice. March 16 it was chloroformed, and, with the exception of an old green-stick fracture of the radius of the left forearm just above the wrist, everything was found to be normal at the postmortem examination.

Sebaceous Glands in Cervix Uteri.—Nicholson believes that the sebaceous glands in the cervix of the uterus in his case were a product of the mesoblastic lining of the cervix.

Spirobacillus Zeylanicus.—Taylor isolated this organism from the stools of a case of postdysenteric colitis. The case is reported in detail.

Chemotherapy of Bacterial Infections.—Experimental proof is afforded by Browning and Gullbransen that by the use of antiseptics a highly virulent and invasive bacterial infection can be overcome while still relatively localized in the living body, although the tissues by themselves are unable to cope with it; further, the evidence indicates that this result has been attained by an actual cooperation of the chemical agent along with the natural defensive mechanisms, i. e., the organisms are not killed through the sole agency of the antiseptic. A strain of pneumococcus rendered highly virulent for mice by repeated passages was used to infect a series of animals intraperitoneally, then, after an interval, watery solution of diaminoacridine sulphate (proflavine), 1:400, in the proportion of 1 c.c. per 20 gm. mouse, was introduced into the peritoneum. That the therapeutic result depends on the combined action of the drug and the tissues on the bacteria, appears from the fact that an amount of antiseptic which too closely approaches the toxic limit may fail to produce cure, whereas smaller doses are effective. Thus, in one series, out of eight mice receiving a dose of from 1:400 to 1:500 proflavine, seven were cured, while out of four receiving a dose of 1:3,000, which is the maximum nonlethal dose, two died with pneumococcal septicemia and one died acutely with other organisms in the heart blood.

Triphenylmethane and Flavine Dyes.—Mueller found that the triphenylmethane dyes seem to show a very definite specificity, now for one and now for another type of organism. Malachite and brilliant green, closely related chemically, affect the streptococcus and the colon bacillus. The two violets, probably the same chemical in different degrees of purity, attack the colon bacillus and *B. pyocyaneus*, while the two blues, again closely related and quite distinct from any of the others, seem specific for gram-positive organisms.

The formation of addition products of the dye with a halide, as in methyl green and iodine green, seems to greatly reduce toxicity for all bacteria, and sulphonation apparently quite destroys it. Tissue cells are inhibited before streptococci in every case by the triphenylmethane dyes. In the case of the flavines, however, the dilution producing inhibition is the same for tissue and streptococci, although other bacteria require greater concentrations. Specific action, while less marked than in broth, runs in a general way parallel to it, while in brilliant green and night blue there is evidence of specific toxicity for tissue cells. From these data one would expect better clinical results from the use of flavine than brilliant green in wound dressings. It is also worthy of note that in every case a greater concentration of dye is necessary to inhibit bacterial growth in the presence of serum and tissue than in plain broth. In no case in this series did an antiseptic show greater toxicity for bacteria than for tissues.

Complementing Power in Guinea-Pig Serum.—The methods described by Bigger are said to afford a satisfactory means of estimating decreases in the complementary powers of serums over considerable periods of time.

Cultural Characters of Anaerobic Bacteria.—Fifteen organisms were studied by Adamson and their cultural characters are described. Thirteen are sporeproducing bacilli, one a nonsporing bacillus and one a diplococcus.

Conduct of Labor and Puerperal Sepsis.—The premise that nature sterilizes the vagina and washes out intruding organisms is defended by Brock as follows: One of the earliest changes in the uterus on conception is edema of the cervix, which steadily progresses throughout gestation. This phenomenon is not due to pressure, because it starts almost with impregnation. Whatever its cause, it subserves a purpose over and above that of increasing the dilatability of the cervix. With the progress of the presenting part, the cervix becomes gradually dilated and subjected to an increasing pressure. As a result, vessels are ruptured, and tears, small or large, occur. The torn vessels are sealed, and from them exudes a copious flow of serum mixed with extravasated blood. The purpose of this serous exudation is, doubtless, physiologic, and it is in all probability bactericidal, resembling the flow of lymph after wounds in other parts. Brock suggests that its role is probably partly to cleanse the vagina and partly bactericidal to retained organisms. While all this is a physiologic process and wholly beneficial to the patient, it becomes far otherwise if vaginal examinations are made the rule in labor. Instead of protection, it may be a menace to life.

Lengthening of Amputation Stumps.—A case is cited by Gallie to show that amputation stumps may be lengthened.

With an osteotome applied in the sagittal plane one half of the terminal 3½ inches of the shaft of the bone was cut free. This piece of bone was slid downward so as to lengthen the femur by 2½ inches, and was then fastened by two long screws of beef bone. The flaps were then dissected up sufficiently far to allow them to be drawn down and closed over the end of the bone. The wound healed by primary union, except for a hematoma, which opened spontaneously and disappeared without infection; otherwise recovery uneventful. Two months later the fragments were solidly united and the patient commenced active exercise of the stump to increase the density of the bone. He is now wearing the ordinary artificial limb and has a very satisfactory stump. The extensive splinting of the bone led to rather profuse hemorrhage. Gallie suggests that this could be avoided by substituting for the method described an ordinary inlay bone graft or a graft driven into the medullary cavity.

Vaccination by Subcutaneous Injection.—Goodall has vaccinated hypodermically approximately 6,000 men and quite a number of officers' children. He uses the ordinary vaccine put up in the small capillary glass tubes, injecting 1 cc. and changing the needle after each injection. The local reaction sets in usually in from two to four days. This local reaction is much like that following antityphoid inoculation and just as variable in intensity. About 8 per cent. of vaccinations proved ineffective, showing but slight local reaction, not more than, perhaps, could have been accounted for by the iodine applied to the skin; in 70 per cent. (approximate only) there was a reaction similar to the usual reaction after antityphoid inoculation, i. e., local swelling, heat, tenderness, slight pain and redness. In a small percentage of cases the reaction was marked, causing swelling and edema of the elbow, and in a few cases edema resulted involving the whole arm and hand. In every one of the 6,000 cases vaccinated hypodermically by Goodall or under his supervision the local condition subsided without any signs other than those of excessive local reaction. After the seventh or tenth day the local swelling and induration subside, leaving a hard nodule in the subcutaneous tissues, usually ill defined at first, becoming later well circumscribed and lasting for about one month. This is quite painless after the first acute reaction. The process differs in no respect from that of an antityphoid reaction, except that the onset is slower and the reaction spreads itself over several days. The general symptoms vary in intensity and do not differ from those of ordinary vaccination. In the 6,000 cases quoted there was not one case of infection.

- *Pneumococci Isolated in Infants' Ward. P. Nohécourt and J. Paraf, p. 687.

Initial Lesion of Pulmonary Tuberculosis in Infants.—The breast fed infant of 13 months contracted tuberculosis from a nurse and developed *splénopneumonic bacillaire* with signs of tracheobronchial glandular involvement. The child threw it all off finally, and six years later not a trace can be found except one small shadow, evidently a calcified gland. This was probably the initial lesion, and around it was a perituberculous congestion so intense that it simulated pleurisy of the right side.

Artificial Pneumothorax in Treatment of Dilatation of the Bronchi.—Rist reports the case of a child of 5½ with a manifest focus of sclerosis in one lung, with bronchiectasia, consecutive to bronchopneumonia from whooping cough and measles two and a half years before. He induced artificial pneumothorax, and a complete cure followed which has persisted for five years to date. This measure should not be applied as the last resort, but, as in this case, before the sheets of the pleura are solidly adherent, and while there is still some sound elastic tissue in the inferior lobe. In the radioscopic surveillance of this case he noted, as with any pneumothorax of the kind, that during inspiration the mediastinum was displaced and the amplitude of the heart beat exaggerated on that side. He also noted that the stump of the left superior lobe swelled up suddenly at each ventricular systole, shrinking to its former size at each diastole. Weil reports two similar experiences, but as the interval had been eighteen years or more the pleural adhesions were too solid for the artificial pneumothorax to prove effectual. Only partial benefit was realized, and this only in one case, but even thus the results are encouraging for this new application of artificial pneumothorax in treatment of dilatation of the bronchi before irreparable lesions are installed.

Lethargic Encephalitis.—Pain and his co-workers remark that this disease seems to be spreading in France, and they report four cases in adults at Angers, with recropcy in one. They comment on the number and diversity of the symptoms. In two cases there were nocturnal attacks of precordial pain, distress, tachycardia and convulsive movements, all recurring for more than six weeks. None of the three survivors have regained their earning capacity during the four months to date. They seem to be crippled in body and one in mind besides.

Antithyroid Treatment of Menorrhagia.—In the case reported by Weil the uterine hemorrhages had kept up for twenty-five days each month for a year, and the woman of 30 had only 2,000,000 erythrocytes and 40 per cent. hemoglobin, while the blood took ten minutes for the clot to form, and coagulation of the venous blood took fifteen minutes. The gums also bled readily but there were no personal or hereditary hemorrhagic antecedents. The woman had a small goiter but no other signs of exophthalmic goiter. He gave tentative organotherapy with thyroid, suprarenal, pituitary and other organ extracts, and tried iron and arsenic—all to no avail. Then he changed to what he calls antithyroid treatment, and a complete cure soon followed. He used for this three teaspoonfuls a day of a glycerin preparation of the blood of goats thyroidectomized over a month before. The literature records the cure by this means of a persisting and recurring hemorrhagic pleurisy in a case of exophthalmic goiter, and the arrest of severe menorrhagia in one woman, a virgin. The hemorrhage-reducing power of this antithyroid treatment seems to be restricted to the genital sphere and complex endocrine disturbance. Ramond has reported a case in which thyroid treatment improved myxedema in a woman of 48, and seemed to cure completely a tendency to multiple recurring hemorrhages.

Necropsy Findings in Pneumonia.—Menetrier classifies the macroscopic findings in 400 pneumonia cadavers. He was impressed among other things by the fact that in the 181 showing tuberculous lesions, in seventy-eight they were of long standing. Fatty degeneration of the liver was almost constant, and in nearly all it seemed to be the direct work of the pneumonia toxin.

Paris Médical

Aug. 2, 1919, 9, No. 31

*Nontraumatic Perinephritic Hematomas. Rapin.—p. 94.

*Ileopelvic Congestion. F. Cathelin.—p. 103.

Nontraumatic Perinephritic Hematoma.—Rapin relates that the hematoma had developed in the man of 35 after scarlet fever. Except for nephritis the kidney seemed sound at the two interventions to evacuate the hematoma. The man died a year later from the progress of his untended nephritis. The diagnosis has rarely been made before the operation, the symptoms indicating merely internal hemorrhage, with sudden violent pain in the kidney region and retroperitoneal tumefaction. Ecchymosis in the lumbar and scrotum region is instructive. The pain differs a little in its site from that with acute pancreatitis, and the kidneys should be examined even when the latter is suspected. Operative treatment has given 50 per cent. recoveries, while all died of the eight under expectant treatment.

Ileopelvic Congestions.—Cathelin applies this term to the cases that used to be called *faux urinaires* or *psychopathes urinaires*, explaining the organic basis for the pelvic plexalgia, pelvic neurosis, or pelvic varicocele. The disturbances are of a functional nature resulting from the abundance of veins in the pelvis. It is an actual venous lake, the vessels and the plexuses closely interwoven. The whole region below the diaphragm is varicose, and vague, deep and radiating pains, disturbance in micturition during the day (not at night as these patients "urinate with their brain") and at night the brain rests), and a nervous or syphilitic taint are the most prominent signs and symptoms. The course and evolution are very slow, and disturbance may take the "false urinary" or the "false genital" form. The subjects may complain of the bladder, kidneys, prostate or urethra, of impotence, spermatorrhea, nocturnal pollutions, etc. There may be no history of gonorrhea or acquired syphilis. Treatment should be by hygiene, psychotherapy, possibly epidural injections, and training the urinary or genital apparatus to better habits. No intra-urethral treatment should be given, no instillation or lavage of any kind, but electrodes to the perineum and above the pubis sometimes give results. He advises as the most important measure to give a sedative at night to ensure sleep, with valerian daily and some depurative every morning, such as a tablespoonful of "horseradish syrup," and, above all, 30 drops daily of the fluid extract of hamamelis, fractioned, before each of the main meals of the day, supplemented by diuretic teas in abundance to dilute the salts and stone-forming elements in the urine. The catheter must never be used in these cases, as it not only could do no good but might transform the patients into true *urinaires* by infecting them or breeding a habit. Severing the pubic veins is a measure that he does not recommend.

*Reconstruction of the Nose. L. Ombredanne.—p. 413.

*Operative Treatment of Ulnar Contracture. R. Le Fort.—p. 414.

*Operative Treatment of Banti's Disease. L. Losio.—p. 415.

Reconstruction of the Nose.—Ombredanne asserts his conviction that if the Italian method had been followed in some recently published experiences with reconstruction of the nose, the outcome would have been still better as there would have been no need to depend on flaps from the vicinity. His success with the Italian method seems to have been remarkable, judging by the cases illustrated. He ascribes his success to certain technical points which he describes in detail, especially the importance of refraining from modeling the nose after the Italian flap from the arm has been cut off. It must be given two months to retract and heal definitely in place before the tip of the nose and the nostrils are modeled into their final shape.

Ulnar Contracture.—Le Fort's illustrations show how the contracture (if there is no bony ankylosis) can be corrected by severing the branch of the extensor tendon that is attached to the first phalanx, severing at the same time the fibers joining the tendon to the perforating fibers of the palmar aponeurosis and the interossei and the lumbricals at their junction with the extensor tendon. All these fibers are cut close to the tendon, which is thus relieved from the inward pull causing the claw hand.

Operative Treatment of Banti's Disease.—Losio recently reexamined a woman of 58 who seemed to be in perfect health although in 1916 he had operated on her for primary splenomegaly with cirrhosis of the liver at the ascites stage—a typical case of advanced Banti's disease. He combined splenectomy with omentopexy, and cites others' experiences to confirm the rational premises and successful outcome of this combined method. The spleen is the organ primarily affected, and splenectomy is indicated whenever the primary splenopathy is capable of entailing cirrhosis of the liver. He warns that every scrap of the spleen must be removed with minute care, and search must be made for possible supernumerary spleens which should also be removed.

*Disturbance in Absorption of Fat by the Intestines. A. Lémierre and others.—p. 425.

*Extraction of Projectiles under Roentgen Control. Gudin.—p. 427.

Symptoms from Wounds of Arteries. H. Mondor.—p. 429.

Disturbance in Intestinal Absorption.—Lémierre and his co-workers review the means at our disposal to detect defective absorption of fat by the bowel, especially when there is retention of bile and disease of the pancreas. They insist that bile is indispensable for absorption of fat by the bowel, while this is but little affected by lack of pancreatic juice. At least, the latter is not indispensable, like the bile. The partial or total absence of absorption of the fat ingested should be regarded as a sign of insufficiency of the biliary apparatus rather than as a sign of insufficiency of the pancreas alone. The pancreas may be decidedly pathologic without the absorption of fats being much disturbed. Previous research in this line has given conflicting findings on account of the inexact methods followed. By direct determination in the blood of the absorbed fats, the findings have always been exact and concordant, and this method they commend as dependable. Chemical tests for fat in the blood are too complicated for general use, but examination of a drop of blood-dust, hemokoniae, is simplicity itself, as all that is necessary is to examine with the ultramicroscope a drop of blood between slides. They studied in the dog the effect on absorption by the bowel of fat ingested after resection of the common bile duct, and also in clinical cases of obstruction of the biliary passages. When bile is completely shut off, no hemokoniae appear in the blood after ingestion of a test meal of fat, and chemical tests of the blood show no difference in the fat content fasting or after the test meal. This estimation of the difference between the lipemia fasting and after the test meal is a much easier method than to determine the absolute fat content. The fat in the blood reaches its height from four to six hours after the test meal, and the examination of the blood should be done during these hours.

Extraction of Projectiles Under Roentgen Control.—The special advantage of Gudin's simple and portable device is that the radioscopic localization can be done in daylight and without changing the position of the patient. In case the roentgen procedure is not available, the device can be used as a simple compass. Seven illustrations of it are given.

*Spa Treatment of Liver Diseases. Willemm.—p. 296.

Tuberculosis of the Jaw.—Ames and Aubanel report the case of a boy of 8 who developed a tuberculous process in one ankle, a year later one in the forearm, and later one in the tibia. Five years after the first symptoms, an abscess appeared in the left lower jaw and pus kept reforming after repeated punctures. The entire left jaw shows notable thickening on radiography, with a zone of less opaque bone in the horizontal ramus. The prognosis of such lesions is grave. In Perrot's compilation of twenty-four cases, only ten of the patients recovered, and this recovery is precarious. In two cases the patients succumbed to tuberculous meningitis. The outlook in the present case seems absolutely bad.

Spa Treatment of Liver Disease.—Willemm explains the factors in the benefit in disease of the liver from a course of mineral waters at Vichy. It seems to stimulate the antitoxic action of the liver and restores the physiologic balance as the poisonous wastes with which the cells were clogged are washed out as by a freshet. Under the influence of the course the leukocytes show important modifications and phagocytosis is whipped up. Analysis of the urine, stools and blood shows the benefit from the waters, in particular on the three great functions of the liver. The power to reduce sugar is regained to large extent, so that diabetics with from 40 to 80 gm. sugar witness its disappearance, and larger sugar contents drop to a third. The waters do not seem to benefit materially dyspepsia of nervous origin or with dilatation of the stomach, but when liver disease is a factor, marked improvement is realized. Symptoms of liver involvement should be sought in all cases of dyspepsia. If the liver is too profoundly diseased for recuperation, the Vichy waters may exaggerate the morbid condition, as in conditions generally in which the reaction to the effect of the waters may be more than the extremely debilitated patients can stand.

- *Wound of the Liver. Soubeiran.—p. 21.
- *Traumatic Hematoma Back of the Omentum. G. Migonac.—p. 81.
- *Phylogenic Tetanus of the Femur. P. Le Dantec.—p. 135.
- *Treatment of Cavities in Bones from Traumatic Osteomyelitis. H. Lefèvre.—p. 140.

Melanic Cancer of Male Breast.—Forge and Chauvin report a case of melanic cancer of the male breast and summarize 18 others they have found on record. The ages ranged from 10 to 69, with 40 as the average. The influence of traumatism seems evident in 4 cases, but heredity as a factor did not appear except in one case. The list includes 5 Frenchmen, 6 Anglo-Americans, 6 Germans and one Italian. The tumor had been noted before the medical examination from one to five years, an average of nearly two and a half years. Long survival is recorded in some cases with early operation before the glands had become involved. In 2 cases two operations were required, and the patients survived three and fourteen years.

Wounds of the Liver.—Soubeiran analyzes 323 cases of war wound of the liver, and compares them with the stab

wounds of the liver in peace, discussing the treatment and the outcome.

Retro-Omental Hematoma.—Migonac remarks that the only treatment for traumatic hematoma back of the omentum is by a laparotomy. In forty-five cases he has compiled, the mortality in all the untreated cases was 100 per cent, and only two recovered in the six cases treated by puncture alone.

Treat of Cavities in the Bones.—Lefèvre noted that cavities after traumatic osteomyelitis, when located in the femur, seemed to be the hardest to cure. He reviews the indications for treatment, and summarizes fifty-six cases from his own service.

- *Hypostoses in Case of Lateral Amyotrophic Sclerosis. A. Barbé.—p. 111.
- *Conceptions of Space, Time and Number. W. van Woerkom.—p. 113.

Experimental Research on Aerial Shock.—Mairet and Durante give photomicrographs of the findings in rabbit brains after exposure to explosions without direct contact. Their extensive research confirms that it is necessary to distinguish between a concussion, a commotion or concussion, and an emotional shock. The effects of concussion from a solid or gaseous agent are focal lesions with attrition. The effects of a commotion are a vibratory shaking up, and this causes diffuse lesions in the elements most readily shaken up, but there is no attrition. The emotional shock is the result of exhaustion and overwork or excesses of various kinds, and its effect is purely functional. The *commotion*, they reiterate, is a *blaise interne* with lesions which differ from those we had been accustomed to observe before the war. The diffuse lesions are extremely minute but extremely numerous, and the resulting symptomatology is often abortive but is always complex—an entirely new field for exploration which may lead indirectly to the solution of many hitherto obscure problems. It may reveal the organic basis for many conditions hitherto deemed pure neuroses. The data presented, they add, renders darker the outlook for the *commotion*s, even the simplest forms, as they show that these immediate war vascular and other lesions may lead to grave and irreparable secondary lesions. Not only will many of them be unable to recuperate, but they seem destined to entail sequelae calling for disability pensions. (Although "concussion" is a good French word, it is never used in this connection, as it has a special meaning of illegal graft in French. "Commotion" is the term preferred in France, and it is being generally accepted elsewhere now.)

The Geometric Sense, Sense of Time and of Numbers.—Van Woerkom describes a case of retrogressing aphasia of the Broca type which emphasizes anew the essential difference between the psychic act of recognition—passive memory—and the psychic act of evocation—active memory.

War Wounds of the Femur.—This is a summary of the experiences and outcome with fracture of the shaft, or both shaft and epiphysis, in sixty cases.

Surgery of Amputation Stumps.—Montemagno discusses the various indications which confront the orthopedic surgeon, and gives an illustrated description of the technique followed under the different conditions. The work is based

on 384 cases of reamputation at the Rizzoli Orthopedic Institute. In fifty-four cases the reamputation had to be bilateral. A number of points are emphasized to guide surgeons at the primary amputation.

War Wounds of the Spinal Cord and Meninges.—Pieri analyzes 119 clinical cases of this kind, observed mostly at an advanced surgical station.

Reconstruction of the Thumb.—Pieri slits the soft parts down to the base of the basal phalanx of the thumb, and prepares this phalanx to serve as the thumb. In the two cases illustrated, the men were able in a few weeks to grasp firmly articles that were not very small with the reconstructed thumb.

Topography of the Fibers of the Popliteal and Ulnar Nerves.—In these two communications a number of cases are described in which peculiar conditions after war wounds remarkably facilitated investigation of the course of the fibers in these nerves, and of the domain innervated by the different fibers.

*Electric Treatment of Causalgia. G. Boschi and G. Tanfani.—p. 540.

Electric Treatment of Causalgia.—Boschi and Tanfani report most gratifying results from the high frequency current in treatment of causalgia, describing a number of typical cases after war wounds. Transient relief followed each application, and the pain grew more attenuated and disappeared completely in from two weeks to two months in about half the cases. This simple treatment should be given a trial if nothing can be found that suggests pressure on the nerve. They apply the current merely in the form of the effluvia.

*Induced Pneumothorax in Treatment of Tuberculous Pleurisy. P. Binda.—p. 554.

Tuberculous Pleurisy.—Binda points out that in treating tuberculous pleurisy we must not overlook the practically invariably accompanying tuberculous process in the lung. For this, we are reduced to general measures and local compression of the lung by induced pneumothorax. This can be applied after evacuation of the effusion and in appropriate cases seems the most rational and effectual method at our disposal. It obviates any disturbance resulting from evacuation of the fluid, and prevents formation of adhesions. Air alone in the pleura is not always capable of preventing the total or partial collapse of the sheets of the pleura. The pneumothorax should be kept up until a connective tissue barrier has been thrown up around the pulmonary focus.

Treatment of Scabies. G. Riva.—p. 599.
*Adaptation of Bacteria. P. Rondani.—p. 599.
*Bone Complications of Typhoid. E. Aievoli.—p. 601.
The Scientific Sources of Modern Stomatology. B. de Vecchi.—p. 606.

Glandular Dystrophy.—Mariotti gives an illustrated description of a case of general pluriglandular dystrophy, predominantly thyroid and genital, in a tall young man with persisting juvenile characteristics. Implantation in the thigh of a testicle just removed from another patient was followed by some improvement, but it proved only brief and transient as the implanted tissue was resorbed.

Influence of Physical Measures on Phagocytosis.—Ciancio reports experiments with human leukocytes in suspension in their own serum, defibrinated, seeking to determine the effect of heat, sunlight and ultraviolet rays on the phagocytosis of bacteria. The germs studied were the staphylococcus, colon bacillus and *Faecalis aequaligenes*. The staphylococcus after heating was more easily incorporated by the leukocytes, and phagocytosis was still more intense after the germs had been exposed to the ultraviolet rays, and most intense of all after exposure to sunlight. The ultraviolet rays seemed to damage

the other germs to such an extent that they were destroyed by the serum before phagocytosis was possible.

Adaptation of Micro-Organisms to the Organism.—Rondani cites some facts which seem to suggest that pathogenic micro-organisms may have their protoplasm altered in time so that they then become susceptible to the action of antihodies which before they resisted, or vice versa. This calls for caution in the estimation of certain biologic reactions, while at the same time it opens new routes for progress, and explains certain still obscure points in infectious diseases. For instance, the self-limiting course in relapsing fever which stops after two or three relapses, while syphilis keeps on indefinitely.

Bone Complications with Typhoid.—Aievoli discusses the bone and joint complications with typhoid and paratyphoid and the importance of bacilli carriers. He insists on the necessity for watching over convalescents and not ascribing to "neuralgia" or "hysteria" any pain in bones or joints. The danger from an overlooked spondylitis is particularly grave on account of the deformity liable to follow if immobilization is neglected. It may not be necessary to apply a stiff corset, but at least the patient should be immobilized in a good position.

*Bacteriology of Influenza in 1918. G. Dore.—p. 281.
*Chronic Hemorrhagic Purpura and Tuberculosis. G. Genesco.—p. 304.

Chronic Purpura and Tuberculosis.—Genesco analyzes the scanty literature on chronic purpura, and reports two cases in which chronic hemorrhagic purpura developed in children of 6 and 2, and was soon followed by symptoms of pulmonary tuberculosis. He thinks this is more than a coincidence, and argues that the purpura was the first manifestation of the tuberculosis; in these cases it was the first and continued the most predominant. In Bensaude's complication of 36 cases of chronic purpura, tuberculosis was manifest in 7 and probable in 5 more; in Momo's 48 cases, tuberculosis was certain in 16. In some of these cases the tuberculosis affected the peritonum, meninges, kidneys, glands or suprarenals instead of the lungs. In conclusion he calls attention to the appearance of giant ecchymoses under the influence of tuberculin treatment.

*Yellow Fever in Peru. J. Arce.—p. 93. Cont'n.
*Trypanosome Found in Blood of Bats at Lima. M. Noriega del Aguila.—p. 134.

Yellow Fever in Peru.—Arce is professor of tropical medicine, and he discusses here the alleged endemic occurrence of yellow fever in the coast towns of Peru, giving a historical sketch of the endemic foci in Guayaquil and Panama and its eradication in Panama. The epidemics of supposed yellow fever in Peru in previous centuries are also described in this instalment of his work. He mentions parenthetically Manson's blunder in stating that yellow fever has been encountered at Cuzco, Peru, at an altitude of 9,000-10,000 feet. Manson was misled by Archibald Smith's report of cases of yellow fever in the coast towns, which he personally inspected, while he accepted as the same disease cases of typhus reported by others from the mountain regions. Smith stated that the points in which the disease on the coast differed from that in the mountains were evidently merely the modifications induced by the altitude and the climate. Smith's statements have never been officially contradicted, although the physi-

cians of Peru never agreed with him, and Arce says it is high time to correct Manson's mistake.

Trypanosome in Blood of Bats.—Noriega reports the finding of *Trypanosoma vespertilionis* in the blood of 7 per cent. of forty bats of the molossus species at Lima. He says that this is the third trypanosome identified in Peru, the others being the lewisi and the duttoni, found in 1904 and 1917, respectively.

- *Chronic Constipation and Vagotomy. C. R. Udaondo.—p. 326.
- Intestinal Tuberculosis. F. Gallart Monés.—p. 335.

Acute Primary Spasm of the Esophagus.—In the first case here described by Martínez the robust woman of 30 found that she was unable to swallow after a fall which did not cause any appreciable lesions. Fluids swallowed were expelled when they reached a certain point in the esophagus. He was able to pass a semiflexible tube down into the stomach but found it difficult to withdraw as the spasm of the esophagus gripped it tight. A faradic current was then applied to the neck and chest, and in five minutes the spasm subsided and there has been no further trouble since. She had had a similar attack of primary spasm of the esophagus seven years before on the occasion of a sudden death in the family, and it had yielded likewise to the faradic current. Its effect could have been only by suggestion, he remarks, as otherwise the galvanic current would have been indicated.

Chronic Constipation and Vagotomy.—Udaondo regards spastic constipation as merely one manifestation of general overexcitability of the autonomic nervous system. This hypervagotomy manifests itself in various ways, with intermittent involvement of different organs, and prominent in this is atonic or spastic constipation, isolated or combined or consecutive. Treatment of this form of constipation should be addressed to the nervous system, and he has been most successful with atropin.

- *Tuberculous Rheumatism. E. Odriozola.—p. 195.
- *Urine Diagnosis of Renal Tuberculosis. C. A. Zevallos.—p. 198.
- *Trichomonas Hepatitis. E. Escamez.—p. 208.
- *Vincent's Angina. J. C. Dianderas.—p. 211.

Tuberculous Rheumatism.—Odriozola reports a case of subacute articular rheumatism that began to develop two days after washing a stream when much fatigued. The features of the case suggest Poncet's tuberculous articular rheumatism, and tuberculin treatment offers the best prospects, beginning with minute doses and repeating the injections weekly, gradually increasing them.

Urine Diagnosis of Renal Tuberculosis.—Zevallos applied the Delbré and Paraf technique for the fixation reaction in 19 persons with kidney symptoms suggesting a tuberculous lesion, and in 12 the outcome was positive, confirmed by the course of the case in all. In a compilation of 81 certain cases, the findings were positive in 79, while inoculation tests were positive only in 60 and direct examination showed a tuberculous focus only in 22. Zevallos used serum from tuberculous patients for the antituberculous serum, not having prepared horse serum available.

Trichomonosis of the Liver.—Escamez has encountered two recent cases and describes the total of five in which *Trichomonas intestinalis* was obtained from the abscess in the liver. Three of his five patients died, but the two latest treated by his improved method, with turpentine and iodine alternately, recovered completely after a two months' course, and have had no recurrence during the three years since.

(His) method was described in THE JOURNAL, May 17, 1919, p. 1501.)

Vincent's Angina.—Dianderas describes a case in his own person in which *Capsicum annuum* seemed to act like a specific. He touched the lesions with the triturated seeds in a semifluid paste, repeating the applications every fifteen minutes at first. Within thirty-six hours only slight traces were left of the gangrenous patches, and healing proceeded rapidly, although deep recesses had been left by the burrowing processes before they had been arrested by this topical medication. The burning from the first applications caused intense salivation and rhinorrhea but in three hours the fever had dropped and the relief was so intense that he slept tranquilly all night. The capsicum is a household remedy in his country, and it seemed to prove its efficacy in his case after failure of all the usual measures.

- Case of True Hermaphroditism. A. Jiménez O'Farrell.—p. 22.

By-Effects of Spinal Anesthesia.—García examined the spinal fluid obtained by lumbar puncture drawn as soon as the patient exhibited symptoms of distress after injection of cocaine into the subarachnoid space. It showed reactions indicating the presence of cocaine, and the symptoms subsided at once after 40 c.c. of fluid had been withdrawn. In others of the twelve cases described the spinal fluid was withdrawn without waiting for symptoms to develop, and none of these patients developed headache or any other symptoms thereafter. His experiences show that cocaine persists in the cerebrospinal fluid up to five hours after even a small amount has been injected. The advisability of withdrawing the toxic fluid at the slightest symptom of intolerance is obvious. The fluid can be withdrawn immediately the analgesia is complete. It is not even necessary to wait for the conclusion of the operation, as the analgesia once installed does not seem to lose in quality when this is done. If simple withdrawal of spinal fluid does not arrest all disturbances, he adds that the spinal canal might be rinsed out.

- Serodiagnosis of Syphilis. E. de Raso.—p. 17.
- *Pulque Yeast. M. Cordero.—p. 24.
- Lymphocytosis in Syphilitic Blood. T. G. Perrine.—p. 29.

The Gaceta.—This journal is the official organ of the Academia Nacional de Medicina, Mexico, and herewith it enters on the first volume of its fourth series, in its fifty-fourth year. Dr. E. Landa is the editor, and it is to be published monthly.

Hematology of Altitude.—Vergara here presents evidence to prove that the polycythemia of high altitudes is the result merely of the concentration of the blood from losses of water, owing to the dryness and rarefaction of the air. This concentration of the blood has a useful purpose in conserving the activity of the gas interchanges, and in promoting the circulation in the rarefied air. His research was done mostly on the residents of the high tableland of central Mexico, and he cites a number of similar findings by others. The average number of erythrocytes in 225 observations was, 6,480,000; Landa found in children 6,185,000, and Vergara in thirty-eight observations in adults found 6,762,236. His large work on life on high tablelands, written in collaboration with Herrera, obtained the Hodgkins international medal of the Smithsonian Institute.

Pulque Yeast.—Cordero suggests that the yeast from pulque be utilized like brewers' yeast.

Case of Addison's Disease. Id.—p. 228.

The Dynamics of the Heart.—Bañuelos tabulates the findings and gives tracings showing the influence of epinephrin, ether, atropin and muscarin on the blood pressure, as compared with the heart beat.

Chronic Colon Bacillus Infection of the Urinary Apparatus.—Mollá relates the details of five cases of chronic colon bacillus infection of the bladder, and emphasizes its resistance to the ordinary measures in vogue for treatment of cystitis. It seems to be aggravated by silver salts. The bladder responds with pain to pressure on the hypogastrium and through the vagina and rectum. The pain may be mild or absent when the bladder is gently compressed through the hypogastrium, but if the hand suddenly releases the bladder, as the latter stretches there is acute pain. The cystitis with this infection is often of the dolorosa type, and there is generally slight terminal hematuria, and exploration with instruments is exceptionally painful, while the capacity and tolerance of the bladder are slight or null, and incontinence is frequent. No other form of cystitis is so liable to concretions and incrustations. Two of the five cases described were in boys of about 11. Recovery has not been complete to date in any of them, but his three patients with colon bacillus pylonephritis recovered completely after nephrectomy. In this latter affection only one kidney is involved, as a rule, and the general health does not suffer so much as with other infectious germs. The accompanying cystitis is generally mild and permits exploration of the ureters. There is seldom a history of hematuria, and tubercle bacilli are never associated with the colon bacilli. The kidney is usually displaced in these cases, and adherent, as these suppurative processes usually develop only in the displaced and adherent kidney. Concretions and incrustations do not develop with colon bacillus pylonephritis, and the large size of the kidney is explained by the almost invariable preceding uronephrosis. The large size and the peculiar predisposition to adhesions render nephrectomy more difficult than is the rule with tuberculous kidneys.

Tuberculosis of the Conjunctiva.—Basterra says that he has encountered both primary and secondary tuberculous lesions

in the conjunctiva, as he describes with numerous microphotographs. He found it more frequent in girls and women than in men; the majority of the patients were between 10 and 30 years old. The conjunctiva of the lids and tarsus is the usual site, but the clinical differential diagnosis is not enough. If the lesion is not very extensive, it yields readily to touching with 50 per cent. lactic acid.

- *Industrial Accidents Injuring the Urinary Apparatus. V. Juaristi.—p. 198.
Radiologic Diagnosis of Appendicitis. J. González Campo and J. González-Campo de Cos.—p. 209.
Dieting for Recalcification. S. Carro.—p. 223.

Industrial Accidents Involving Urinary Apparatus.—Thirteen illustrations accompany Juaristi's account of his experience with grave industrial accidents causing rupture of the kidney, fracture of the pelvis, etc., and the measures applied to correct conditions. Industrial accidents involving the urinary apparatus frequently entail serious inconvenience from fistulas, etc., loss of procreating power, and there is always danger of secondary stenosis. All this should be borne in mind in estimating the workman's compensation. Serious indirect injuries of the urinary apparatus from fracture of the spine generally soon terminated fatally in his experience. In other indirect cases there was merely transient paresis of the bladder.

Double Uterus. Cospedal.—p. 201.
*Hernia of Pregnant Uterus. J. Ledesma.—p. 205.

Radioactivity.—Mme. Curie's address was briefly summarized, Aug. 9, 1919, p. 459.

Hernia of Pregnant Uterus.—Ledesma gives drawings of a pregnant woman of 42 with a huge hernia which did not interfere with bowel movements. She had long been subject to reducible inguinal hernia, but at about the middle of this seventh pregnancy the hernia became suddenly immensely larger and could not be reduced. Soon she felt fetal movements in it, and a committee from the Academia Médico-quirúrgica was appointed to study the case and do cesarean section at the proper time. A viable child was thus delivered from the hernia, and interesting data recorded from auscultation of the uterus thus exposed for research. The uterus was reduced afterward and menstruation has been regular since.

Hypochloric Treatment of Puerperal Infections. V. Valdes.—p. 250.
Importance of Analysis of the Sputum. M. Bañez.—p. 252.

Malaria in Mexico.—Torres here concludes his long article on this subject, discussing the mosquitoes found in Mexico, the ravages caused by the disease in that country and the means best adapted to eradicate it. He estimates at 100,000,000 pesos the annual losses from malaria, as the very lowest possible figure.

Pneumococcus Infection of the Genitals.—Torrella reports the case of a woman, a virgin, who for twenty years had had a purulent discharge from the vagina. He found that the uterine cervix was of a wine color, and the walls of the vagina congested. The pneumococcus was found in pure cultures, and recovery soon followed injections of an auto-vaccine by Wright's method. Similar success was realized in a second case, the patient a young man who had had an abscess in the perineum after an attack of supposed gonorrhea. A mucopurulent discharge from the meatus revealed

the pneumococcus in pure cultures, and under an auto-vaccine the cure was soon complete. Torroella suggests that these pneumococcus infections may be sometimes mistaken for gonorrhea, and this may explain the failure of treatment of gonorrhea in some cases. He remarks in conclusion that the clinic does not present now any fundamentally new phenomena which were not already present in the clinical pictures of a century or two ago, but they were overlooked then. If we overlook some of them now we show culpable neglect of the diagnostic means at our disposal.

Septic Infection in the Newly Born.—Ramírez says that both of the two infants died. There was a case of scarlet fever in one of the families at the time.

Revista de Medicina y Cirugía Prácticas, Madrid

July, 1919, 124. Nos. 1362-1364

*Laryngectomy. R. Botey.—p. 41.

*Treatment of Rebellious Hiccup. D. F. Venegas.—p. 121.
Hemorrhagic Purpura. E. Guínez de Azcarate.—p. 124.

Laryngectomy.—Botey calls attention to a special drawback of the Gluck technic for laryngectomy and describes how to avoid it.

Rebellious Hiccup.—Venegas has promptly relieved the patient in some cases by compression of the diaphragm. This can be accomplished by distending the stomach with gas, having the patient swallow a mixture of 5 gm. each of citric acid and sodium bicarbonate. The gas generated by this pushes up the diaphragm and this may arrest tenacious hiccup. Another means of compressing the diaphragm is by having the patient lie supine, and flexing the legs and then flexing the thighs to the extreme on the abdomen. This pushes up the contents of the abdomen, and the position should be maintained for ten minutes at least, or until the spasm of the diaphragm has relaxed. The same measure can be applied anew if the hiccup returns. He has never tried the gas distention of the stomach as the mechanical flexing of the thighs on the abdomen always answered the purpose in time.

Pernicious Anemia as an Independent Disease.—Van Thienen examined the blood of 100 healthy persons to ascertain if there was any connection between the number of red corpuscles and the catalase content of the blood. His findings suggested the advantage of a catalase index, the quotient obtained by dividing the catalase content figure by the number of millions of red corpuscles. This represents the milligrams of H₂O₂ generated per million corpuscles. This index in health, with the normal average of 27.54 for the catalase figure, averages 0.14. This catalase index is thus an important and in investigating pathologic blood. It is much more enlightening than the catalase figure alone. He tabulates this index from 10 cases of cancer, ranging from 5.0 to 6.5; in 10 cases of tuberculosis, range 5.6 to 6.5; 10 of acute hemorrhage, range from 5.4 to 6.6; 7 of severe anemia, range 5.0 to 6.5; 7 of leukemia, range 4.6 to 7.6, and 17 cases of pernicious anemia. In the latter group the range was from 1.0 to 17.6 with one exception in which it was 9.2. In 24

persons with pernicious anemia, over 60 tests all confirmed this extraordinarily high catalase index in this disease, and in this disease alone. This seems to justify its acceptance as a separate disease.

Ideas of Space in Imaginary Conceptions.—Grünbaum asked persons to close their eyes and then summon before their "mind's eye" the conception of a red ball. Then to the question where they saw the ball, some said "A few steps in front"; others "To the left" or "right." This sense of direction in imaginary conceptions was tested from various points of view as he describes.

The Thread Test of Gastric Ulcer.—Koelensmid remarks that Einhorn's thread is a very sensitive test for occult blood in the stomach. But a positive reaction does not necessarily indicate an ulcer. In 100 applications of the test the findings very rarely conflicted with what was known of the stomach conditions otherwise. In 3 cases of cancer there was no reaction; in 61 cases of certain ulcer in stomach or duodenum the reaction was positive in 44; negative in 2, and dubious in 15. In 43 cases of neurosis, atony or other nonulcer cases, the reaction was negative in 31, dubious in 10, and positive in 2. The test thus has strong corroborative value, and repeated negative reactions render the diagnosis of ulcer in stomach or abdomen highly improbable.

Psychoses After Influenza.—In each of the six cases described recovery was prompt. Schade treated them on the basis of a psychosis from toxic action, with purging, restriction to milk, no sedative drugs. The continuous bath proved very useful in two of the cases.

*Acidosis in Diabetes. E. B. Salén.—p. 186.

Clinical Significance of Tube Casts. U. Quensel.—p. 211.

Research on Diabetes.—Petré records the details of twenty cases of diabetes in which he experimented to determine the conditions under which and the degree to which the tolerance for carbohydrates could be increased by an appropriate diet. The tabulated data confirm that the shorter the duration of the diabetes the better the outlook, as also with a tolerance of 40 gm. and over at the beginning of treatment. This harmonizes with Naunyn's dictum that a case of diabetes can be classed as mild only when the sugar can be banished from the urine with reduction to 60 gm. of bread. By reducing the carbohydrates in the food we not only induce symptomatic improvement, but as the tolerance for carbohydrates increases under this, we can assume that it is an actual rational treatment of the disease, modifying perhaps certain functional factors at least. By systematic and persevering treatment for one, two or three months he increased the tolerance in many of his cases by 33, 50 or 91 to 118, and even to 128 with longer treatment.

Subphrenic Abscess.—Jacobaeus found on thorascopy after exploratory puncture that the lung and pleura were hyperemic but that the diaphragm bulged upward on that side, and its surface showed signs of inflammation and fibrin deposits. The suspicion of an abscess just below was confirmed by the operation done at once. In a second case the diagnosis wavered between empyema and subphrenic abscess until air was injected after fluid had been aspirated by puncture. Roentgen examination then showed the diaphragm pushed up by the air bubble, corroborating the assumption of subphrenic abscess. As the pus soon grew sterile no operation was attempted.

Diabetic Acidosis.—Salén presents evidence to the effect that there is no regularity in the proportional urine content of the acetone bodies, and that beta-oxybutyric acid may occur in large amounts even when the total acetone content may be too small to elicit differential reactions. The beta-oxybutyric content can be estimated separately by oxidation to obtain the titrable acetone. For this he found Engfeldt's method II simple, reliable and convenient, and has still further simplified it, as he describes.

EPIDEMIOLOGY AND RECENT EPI- DEMICS *

SIMON FLENNER, M.D.
NEW YORK

Since the last congress, held in 1916 in the midst of the racking uncertainties of the great war, notable events and serious calamities have befallen the world and arrested the attention of all thoughtful men. A bitter and passionate military contest has been brought to a hopeful conclusion; but because of the unparalleled cost of the struggle, in lives and in treasure, deep unrest, revolution even, starvation and disease are prevailing over a large part of Europe, while also within the three year period elapsed between the last congress and the present one three destructive epidemics of disease have ravaged the United States and the world.

Hence it has seemed fitting to me that on this occasion and before this representative body of medical men we should pause for a brief period in order to review, as it were, our knowledge of epidemics and at the same time of the practical hygienic measures, based on this knowledge, which we have already put or in ordinary course of events may reasonably hope to put into motion against the spread of these epidemics, so that we may form a judgment of the efficacy of such measures and arrive possibly at new points of view from which to launch a more decisive attack. Moreover, it seems imperative that we should consider not only the sum of our knowledge of epidemics, but also certain facts relating to the populations affected which react powerfully on the successful application of the hygienic means available.

Three epidemic diseases—poliomyelitis, streptococcus pneumonia and influenza—have been especially destructive in the western world during the past three years; also, because of certain common characteristics, they are well adapted for the purpose I have in view.

POLIOMYELITIS

In the United States we are becoming increasingly familiar with epidemics of poliomyelitis. Prior to 1907, infantile paralysis was a rare disease in this country; since then it has prevailed fitfully every summer and autumn, and in one notable instance, at least, in the winter season,¹ claiming victims by the score or hundred, until in 1916 an outbreak of unprecedented severity, with its center of violence in New York State, swept over a considerable number of states.

Fundamental knowledge of poliomyelitis may be said to have grown rapidly since Wickman's epochal clinical studies published in 1907. We are, indeed, today in possession of precise information covering essential data with regard to the nature of the inciting micro-organism, notwithstanding its very minute size, and also concerning the manner in which it leaves the infected or contaminated body within the secretions of the nasopharynx chiefly and gains access to another human being by means of the corresponding mucous membranes and apparently in no other way. Moreover, the inciting virus so called, up to the present time and notwithstanding many and assiduous efforts, has not been detected apart from the infected or merely contaminated human being, and there is therefore no foundation in ascertained fact for an assumption that the virus is conveyed to persons otherwise than by other persons who harbor it.

STREPTOCOCCUS PNEUMONIA

The second example, namely, that of streptococcus pneumonia, presents a phenomenon almost, if not quite, new among the epidemic diseases. It appears as if during the winter of 1917-1918 there occurred in several localities within the United States, and also, but in less degree, in France, at least a great increase in the incidence of a type of pneumonia which previously had been very infrequent. It appears also that the greatest number of cases and of fatalities arose in the United States in the military cantonments; that the disease first prevailed as a secondary pneumonia following measles; but that before long the severity of the infection was such that cases of primary streptococcus pneumonia began to arise. Moreover, at this juncture the disease spread from the military to the civil populations.

The nature of the micro-organism inducing this form of epidemic pneumonia is indicated in the name which the disease has come to bear. The difficulty in this instance has not been in finding out the inciting microbe, but rather in differentiating the streptococci responsible for the epidemic disease from streptococci possessing the ordinary pathogenic properties, or even from those of saprophytic nature so commonly present on the upper respiratory mucous membranes without provoking widespread disease. However, numerous studies of the bacteriology of this epidemic of pneumonia, at distinct and often widely remote cantonments, showed that the microbial incitant was in almost every instance *Streptococcus hemolyticus*. Moreover, because of the wide occurrence of the epidemic pneumonia, this type of streptococcus could be found in normal throats and as a secondary invading micro-organism in the lungs in cases of ordinary lobar pneumonia.

* President's address, read before the Tenth Congress of American Physicians and Surgeons, Atlantic City, N. J., June 16, 1919.

1. At Fairmont, W. Va.

monia. Thus far very little progress has been made in the classification of streptococci, which form a class apparently even more heterogeneous than the pneumococci.

The point I wish to emphasize is this: Regarding epidemic diseases in general we are wont to assume the introduction from without, and usually from a distant locality, of a special kind or race of micro-organism which is held directly responsible for the epidemic ensuing. In the instance of the epidemic pneumonia, no such importation or new introduction of the inciting streptococcus needs to be or actually is assumed. It is so probable as to amount to practical certainty that the excessively virulent *Streptococcus hemolyticus* was developed by a process of selection, through successive transfer from person to person, and by gradual enhancement of its invasive properties.

We are in this case on safe grounds when we assert that the inciting streptococcus is always personally borne; that is, that it leaves the respiratory organs of one person to be introduced on the corresponding organs of other persons, and in no other manner. In other words, the mechanism or mode of infection in epidemic streptococcus pneumonia, as in poliomyelitis, may be said to be clearly apprehended.

INFLUENZA

The case of influenza, the third and perhaps the most important example cited, is quite different, since wide divergences of belief and opinion regarding the nature of the inciting micro-organism and the manner of infection still prevail. The reasons for these differences are several, but the most important, perhaps, relates to the common observation of the manner of spread or attack of the disease. To the casual observer there is something uncanny in the way influenza strikes down its victims. While other epidemics proceed from bad to worse, with at least progressive increases of intensity, influenza seems to overwhelm communities over even wide stretches of territory as by a single, stupendous blow. While in the one case the gradually accelerating rate of speed of extension may be taken to indicate personal conveyance of the provoking micro-organism, in the other the sudden wide onset appears the very negation of personal communication.

Hence the invoking of mysterious influences, the revival of the notion of miasm and similar agencies, to account for this phenomenon. Indeed, the public mind in general lends itself readily to such formless concepts, for the reason that there still resides in the mass of the people, even in the more enlightened countries, a large uneducated residue of superstition regarding disease. One does not need to look far or dig deep in order to uncover the source of this superstition. We have only recently emerged from a past in which knowledge of the origin of disease was scant, and such views as were commonly held and exploited were mostly fallacious. It is, indeed, very recently, if the transformation can be said to be perfect even now, that the medical profession as a whole has been completely emancipated. All this is very far from being a matter of remote importance only, since in the end the successful imposition of sanitary regulations involves wide cooperation; and until the majority of individuals composing a community is brought to a fair level of understanding of and belief in the measures proposed, serious and sustained endeavor to enforce them is scarcely to be expected.

And yet no better instance of a communicable disease could perhaps be invoked than influenza to exorcise the false idea of the mysterious origin of epidemics. To dwell solely on the sudden and overwhelming stroke of the disease is wholly to overlook the significant incidents that precede the mass infection, because they are of such ordinary nature and lack all dramatic quality. Accurate observers noted long ago that influenza in its epidemic form did not constitute an exception to the common rule governing epidemic diseases, which were obviously associated with persons and their migrations. What the early students made out by tracing the epidemic backward to its point of departure, more modern observers have confirmed by carefully kept records, often graphically compiled, as in the excellent instance of the Munich records covering the epidemic of 1889-1892, which can now be supplemented by a number of similarly constructed records of the epidemic just passed. These detailed records show convincingly a period of invasion during which there is a gradual rise in the number of cases, to culminate, within a period variously estimated at from one to three weeks, in a widespread, so-called "explosive" outbreak of the disease.

It happens that the early cases of epidemic influenza tend not to be severe, chiefly because they rarely are attended by pneumonia and hence are frequently mistaken, and the confusion in diagnosis is resolved only when the full intensity of the epidemic is realized. In the meantime, rich opportunity has been afforded for the free and unrestricted commingling of the sick and the well, of doubtless healthy carriers of the inciting agent and others, until so high a degree of dissemination of the provoking micro-organism has been secured as to expose the entire susceptible element of the population, which happens to be large, to an almost simultaneous response to the effects of the infecting microbe.

Deductions of like import can be drawn from the geographic movements of influenza epidemics. In eastern Russia and Turkestan, influenza spreads with the pace of a caravan, in Europe and America with the speed of an express train, and in the world at large with the rapidity of an ocean liner; and if one project forward the outcome of the means of intercommunication of the near future, we may predict that the next pandemic, should one arise, will extend with the swiftness of the airship. Moreover, not only is this rate of spread determined by the nature of the transportation facilities of the region or the era, but towns and villages, mainland and island, are invaded early or late or preserved entirely from attack according as they lie within or without the avenues of approach or are protected by inaccessibility, as in instances of remote mountain settlements and of islands distant from the ocean lanes or frozen in during winter periods.

It is desirable, in the interest of clear thinking, to carry this consideration of the characteristics of epidemic influenza a step farther. A feature of the epidemic disease of particular significance is the tendency to recur, that is, to return to a stricken region after an interval, usually of months, of relative quiescence. Thus the beginnings of the last pandemic in western Europe and the United States have been traced to sporadic cases appearing in April, May and June, possibly even earlier in certain places, while the destructive epidemic raged during September, October and November of 1918. There are very good reasons for believing that in itself influenza is not a serious

disease, but that its sinister character is given by the remarkable frequency with which it is followed, under particular circumstances, by a concomitant or secondary pneumonic infection to which the severe effects and high mortality are traceable. Now it is this high incidence of pneumonia, the product of invasion of the respiratory organs with bacteria commonly present on the upper respiratory mucous membranes—streptococci, pneumococci, staphylococci, Pfeiffer's bacilli, and even meningococci—that stamps the recurrent waves of the epidemic with its bad name.

If we compare the pneumonic complications of influenza with those which arose in the cantonments in 1917-1918, first as attendants of measles and later as an independent infection, we note immediately that in both instances the severe effects and high fatalities arose, not from bacteria brought or imposed from without, but from their representatives which are commonly resident on the membranes of the nose and throat in health. Whatever we may have to learn of the micro-organism inducing measles, still undiscovered, and of influenza, still under dispute, and their mode of invasion of the body, no one would question that the bacteria inducing pneumonia are personally borne.

EFFICACY OF PUBLIC HEALTH MEASURES

With these various considerations before us, we may now discuss the question of the efficiency of our public health measures in diminishing the incidence of epidemic diseases. It should now be evident that our three examples are essentially instances of respiratory infections, that is, diseases in which the inciting micro-organism enters the body by way of the air passages, although not necessarily, as in poliomyelitis, directly injuring those parts. Protection in diseases of this class is not to be secured by applying sanitary measures on a wide scale to an extraneous and inanimate source of the infectious micro-organisms, as to water supplies contaminated with the dejecta of typhoid patients, or even to inferior animal species, such as the mosquito or the rat, which act as intermediaries in conveying the germs of yellow fever or of infectious jaundice; but it is alone to be attained by methods of personal hygiene, applied on the individual scale of safeguarding one person from another, the most difficult of all hygienic regulations to enforce.

Returning now to epidemic poliomyelitis, we may fairly claim that we are in possession of the essential facts which, if widely applicable, should enable us to control the spread of that disease. But we can, I think, hardly claim that up to the present time our accomplishments in that direction have been remarkable. It is sufficient merely to compare the curve of incidence of the Swedish epidemic of 1905, before the nature and mode of infection of poliomyelitis were known, with those of the last several years, in Massachusetts and New York State for example, in order to conclude that the progress of the epidemics in the several places was practically identical.

And, indeed, this is what might be expected in view of the difficulties surrounding the prompt and accurate diagnosis of poliomyelitis in its atypical and abortive, often ambulant forms. Once the disease is introduced under conditions favoring its epidemic spread, a wide dissemination of the inciting micro-organism takes place, and a constantly increasing number of persons becomes exposed to its presence before any restrictive measures are put into effect, and indeed also after they

have been applied. In the case of poliomyelitis, as in that of influenza itself, a wide distribution of the infectious agent precedes the enforcement of preventive sanitary regulations. These considerations do not, of course, warrant intermission of the protective measures now in use, which undoubtedly save many individuals from exposure and thus from potential attack; they do, however, offer an explanation of why, up to the present time, greater success has not attended efforts at control once the epidemic is under full way.

The case with the epidemic pneumonias is of another order: They represent theoretically two diseases which should respond to methods of control based on our knowledge of their mode of infection. In the epidemic streptococcus pneumonia and the pneumonia following influenza we are dealing with pathologic conditions in which not a newly introduced, extraneous micro-organism is operating widely and insidiously, but one in which the active microbes concerned are examples merely of intensified races of common and almost omnipresent species belonging to the flora of the nasopharynx. The infectious agents in these instances are contained within the nasal, buccal and bronchial secretions, and are disseminated in the sprayed material which is coughed or otherwise thrown into the surroundings of the patients. The lesson, therefore, to be derived from the severe experience of the recent pneumonia epidemics is to the effect that measles and influenza patients are not to be assembled into large groups or kept in open wards, but should be placed in separate rooms or cubicles, where they and their attendants may be preserved as far as possible from sputum droplet contamination. In the instance of epidemic pneumonia, a chain of direct infection from one patient to another tends to be established, and hence the sanitary control of those diseases is to be sought through the breaking, as it were, of this vicious circle.

A distinction has now been intimated in the possibilities of direct sanitary control between the two epidemic diseases—namely, poliomyelitis and influenza—introduced from without, and the pneumonias, which are mere, if intense, exaggerations of sporadic diseases ordinarily prevailing. I propose now to lay before you a suggestion as to means of attacking the exotic epidemic diseases which may come to merit serious attention.

ERADICATION OF DISEASES IN ENDEMIC FOCI

Epidemic diseases in the commonly accepted sense have fixed locations—the so-called endemic homes of the diseases. In those homes they survive without usually attracting special attention often over long periods of time. But from time to time, and for reasons not entirely clear, these dormant foci of the epidemics take on an unwonted activity, the evidence of which is the more frequent appearance of cases of the particular disease among the native population, and sooner or later an extension of the disease beyond its endemic confines. Thus there are excellent reasons for believing that an endemic focus of poliomyelitis has been established in northwestern Europe from which the recent epidemic waves have emanated.

Similarly, there are excellent reasons for regarding the endemic home of influenza to be eastern Europe, and in particular the border region between Russia and Turkestan. Many recorded epidemics have been shown more or less clearly to emanate from that area, while the epidemics of recent history have been traced there with a high degree of conclusiveness. From this ca t-

ern home, at intervals usually of two or three decades, a migrating epidemic influenza begins, moving eastward and westward, with the greater velocity in the latter direction.

Now since the combating of these two epidemic diseases, when they become widely and severely pandemic, is attended with such very great difficulty and is of such dubious success, and this notwithstanding the prodigious public health contests which are waged against them in which the advantages are all in favor of the invading micro-organismal hosts, it would seem as if an effort of central rather than peripheral control might be worth discussion. According to this proposal, an effort at control amounting even to eventual eradication of the diseases in the regions of their endemic survival would be undertaken, an effort, indeed, not occasional and intensively spasmodic, as during the pandemic excursions, but continuous over relatively long periods, in the hope that the seed beds, as it were, of the diseases might be destroyed.

That such an effort at the eradication of a serious epidemic disease may be carried through successfully, the experience with yellow fever abundantly proves. In attacking that disease, the combat was not put off until its epidemic spread had begun and until new territory, such as New Orleans, Jacksonville and Memphis, had been invaded; but the attack was made on its sources at Havana, Panama and now Guayaquil, to which endemic points the extension into new and neutral territory had been traced.

I do not disregard the essential fact, in bringing this suggestion forward, that the control at its sources of yellow fever is quite another and probably far simpler problem than the control in their epidemic foci of poliomyelitis and influenza. It is, perhaps, unnecessary to go far into the reasons why the latter would doubtless prove to be far more difficult of accomplishment than has been the former. I am not now engaged in presenting a plan of operation or proposing that the attempt at eradication be made immediately. Our knowledge of all the facts involved in the epidemiology of poliomyelitis, and especially of influenza, may still be too imperfect for immediately effective action. But the very magnitude of the problem of these otherwise uncontrollable epidemic diseases invites to an imaginative outlook which, while perhaps unrealizable today, may not, in view of the rapidly advancing knowledge of the infectious diseases, be hopelessly out of reach tomorrow.

Nor am I insensible to the labor and cost in money and talent which the setting out on such an ambitious enterprise would entail. But here, at least, is a world problem of such proportions and nature as to invite the participation of all the scientifically advanced countries in a common effort to suppress one of the most menacing enemies of civilized man and of human progress.

In proposing to strive for the high achievement, not merely of parrying the blows struck by destructive epidemics, but of rendering them impotent to strike in the future, we may pause for a moment to reflect on the different ways in which peoples react to great calamities, such as those brought by war and by disease. As the results of a cruel and devastating war, revolutions in governments supposed the most stable may occur; no such result follows on still more devastating epidemics. The recent epidemic of influenza claimed, possibly, more victims than did the great war,

and the losses to the world in emotion spent, treasure consumed, and progress impeded are incalculable; yet, through a fortuitous circumstance of psychology, from the one calamity the world may emerge chastened, perhaps even bettered, while from the other, because of a depth of ignorance amounting often even to fatalism, mankind may largely miss the deep meaning of the lesson.

USE OF RADIUM IN FIFTY CASES OF UTERINE HEMORRHAGE

FROM CAUSES OTHER THAN CARCINOMA OR MYOMAS *

S. M. D. CLARK, M.D.

Professor of Gynecology, Tulane University of Louisiana School of
Medicine
NEW ORLEANS

Radium being comparatively a new agent, it is premature to take the position that it has yet reached its maturity or possibilities. As all innovations do, it is now running the critical gamut. In one camp it is unconditionally condemned, while in the other it is equally acclaimed. Where such contention exists the truth is found in the midway position.

Though radium is yet in its developmental period, and though already we have abandoned some of our earlier fondest hopes, still, in the past five years, there have been deduced certain well established clinical facts.

Menstruation is a complex process influenced by innumerable factors, ranging from undeveloped organs, defective endocrines and new growths down to constitutional dyscrasias. In many instances its derangement is a local expression of a constitutional condition; therefore it is most difficult correctly to divide cases of uterine bleeding, of these types, into segregated pathologic groups. In some instances the true pathology is not understood. For the purpose of pre-entation, the cases have been divided into three nominal groups.

GROUP I. HEMORRHAGE IN YOUNG WOMEN

In Group I are placed those cases in which there is an excessive bleeding, with no marked local discomfort, but a decided constitutional impairment resulting from too great a loss of blood. In many of these cases there is no discernible anatomic wrong. Curetting, organotherapy and constitutional remedies fail; the bleeding continues, and in severe cases something radical must be done. What this "something radical" must be reduces itself to the removal of some of the organs, or to allowing the future welfare of the young woman to be jeopardized. Surely many of us have encountered such cases, and the action to take presents a serious problem.

If radium does not act, as we believe, entirely through altering ovarian function, but rather by altering the endometrium and myometrium, then it seems that this is a most valuable field for its use. The literature contains some encouraging reports, and it appears reasonable, as we improve and refine our technique, to expect some substantial help. Certainly it would be most valuable to know that excess bleeding could be controlled and the menstruation not suppressed.

Our experience has not been extensive in this group. In one of five cases there is one in which, by the use of

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, June, 1919.

small, graded amounts of radium, the flow was returned to normal. In another case, an effort to check the flow by graded doses failed, and the treatment had to be pushed on to complete cessation; but even this was better than an abdominal operation.

ILLUSTRATIVE CASES¹

CASE 1 (62447)—History.—Miss R. B., a schoolgirl, aged 17, began menstruation at the age of 12 years. The flow was very profuse at the first menstruation and has continued so. She was operated on, June 5, 1917, and a curettage was performed. Since July 17, 1917, she had had practically a continuous vaginal bleeding. Three applications of radium were given, of 1,500 mg. hours.

Result.—Complete suppression of the menses followed.

CASE 2 (57958)—History.—A woman, aged 28, had a cyst removed from the right ovary when she was 22. Four months ago the menstruation began to be excessive and resulted in a flow lasting twenty-five days. She was curetted twice. Four treatments with radium of 3,850 mg. hours were given.

Result.—There was complete cessation of menses.

CASE 3 (55149)—History.—A woman, aged 33, for several years had had very irregular menstruation, sometimes lasting twenty-eight days. She was operated on for suspension, with no relief. One treatment with radium of 750 mg. hours was given.

Result.—The menstruation returned to a normal and two day type.

CASE 4 (57943)—History.—A girl, aged 16, started menstruation at the age of 13 years. It was very scanty and irregular. The uterus was curetted, Sept. 15, 1917, after which the menses stopped for three months, and the patient then bled continuously for two months. A small amount of radium was used from an outside source with no relief. Treatment of 1,275 mg. hours was given.

Result.—Two treatments produced a cessation of the menses.

CASE 5 (57783)—History.—Mrs. E. J., aged 25, began menstruation at the age of 14 years, and was made very sick from its inception. The bleeding lasted eight weeks, coming in large clots, and the flow was profuse. The menses were never regular. She had had one living child and two miscarriages, the last one a year ago, followed by four months of bleeding. She had had numerous operations. For the past year she had menstruated twice a month, each period lasting from six to seven days. For the past two months she had had a continuous uterine bleeding. Four applications of radium were given, the first of 75 mg., with eleven hours' exposure, and the remaining three of 50 mg., with eleven hours' exposure.

Result.—The condition was entirely relieved.

GROUP 2. AGGRAVATED AND INTRACTABLE DYSMENORRHEA

Cases of violent dysmenorrhea which have resisted all treatment, and in which the general health is markedly impaired, are placed in this group. The affection is most frequently seen in the neurotic type who are reluctantly yielding to advancing years and are as yet unmarried. It is commonly observed in teachers, or in those lately beginning to work, their mission in life still unsettled. The patient has about ten comfortable days in a month, the rest being spent in bed or in struggling to keep up during the premenstrual or the postmenstrual storm. In many of these patients there may be found no anatomic wrong, but the distress is there and is gravely altering her life. We have all had these rebellious cases, in which endocrines, stem pessaries, curetting and climatic changes fail, and in which it is imperative that something be done. As a final measure, if the life is to be useful, menstruation must be stopped.

1. Publication of the cases reported in this paper is made possible through the courtesy of the Radium Institute of New Orleans. This institute is composed of eight physicians of New Orleans, of whom the author is one.

We know that radium will cause the cessation, and we know further that the treatment is less painful and upsetting than an ablation operation and, still further, that it does not seem to be followed by as intense nerve disturbances. Twelve such cases are here reported, complete relief being obtained in all, chiefly through suppression; but in one instance the treatment relieved the pain, and normal menstruation continued, just as resulted in Case 3 in the preceding group.

ILLUSTRATIVE CASES

CASE 6 (64044)—History.—Miss L. S., aged 35, a school-teacher, began menstruation at the age of 14 years and has always suffered pain, but had gradually grown worse in the past four years. She had been unable to teach in this time during her period. She suffered intense headache and backache, and her general health had been markedly impaired. She scarcely recovered from one month's epoch before another appeared. The organs were normal to palpation. A dilatation and curettage were performed and a stem pessary applied, without relief. She was given three applications of radium of 50 mg. and ten hours' exposure each.

Result.—A complete suppression of menstruation and a marked improvement of general health have followed.

CASE 7 (57686)—History.—Mrs. P., aged 28, who began menstruation at the age of 15 years, suffered severe pain and stayed in bed two days each month. She had been married two years, but had no children. She was operated on, March 13, 1913, having the left ovary removed and part of the right. Her general health improved after the operation, but at the menstruation period she suffered severe pain all over the abdomen, and was forced to remain in bed, with frequent urination during the period. Five applications of radium were given, three of 50 mg., with ten hours' exposure, and two of 75 mg., with ten hours' exposure.

Result.—Suppression of the menstruation followed.

CASE 8 (62803)—History.—Mrs. V. B., aged 23, a saleswoman, began a normal menstruation at the age of 13, which gave her no trouble until Feb. 14, 1917, when the flow became profuse and very painful. She was curetted in April, 1917. The appendix was removed, May 15, 1917. The flow had been practically continuous since the April operation. The patient suffered great pain in the back, and general discomfort, and was anemic. She was given a treatment of 50 mg. of radium, Aug. 26, 1917, for a ten hour period, 50 mg., Sept. 9, 1917, and 25 mg., Sept. 19, 1917.

Result.—Complete relief followed.

CASE 9 (65262)—History.—Mrs. P. D., aged 31, who menstruated at the age of 13 years and thereafter regularly and normally, and who had been married fourteen years, having one child, aged 11 years, was operated on four years ago. An appendectomy was performed and a laceration sutured. For the past few years menstruation had been very scant, but the pain was so severe that it necessitated the use of hypodermic injections of morphin. This condition gradually grew worse. Four applications of radium were given, two of 50 mg. and two of 75 mg., ten hours' exposure each.

Result.—Complete relief followed.

CASE 10 (60654)—History.—Mrs. R. H., aged 33, who began menstruation at the age of 15 years, had been married eleven years, having no pregnancies. She had always suffered excruciating pains at the menstrual period, going to bed three days, and had passed large clots of blood. The flow was very profuse. Five applications of radium were given, each of 50 mg. and ten hours' exposure.

Result.—The menstruation was suppressed and there was complete relief.

CASE 11 (57713)—History.—Miss H. H., aged 30, began menstruation at the age of 14 years, and it was regular until she was 17, when it became irregular and developed pain. The pain had gradually grown more intense and she had to remain in bed one week. The flow was very profuse, especially in the past six months. Six applications of radium were given, each of 50 mg. and ten hours' exposure.

Result.—Complete relief followed.

CASE 12 (53965)—*History*.—Mrs. P. G., aged 25, who had been married four years, suffered with dysmenorrhea before and after marriage until the birth of her child. The appendix was removed, the ovary resected and the uterus suspended shortly after her confinement. She then suffered with pains in both sides, and with a profuse menstruation, lasting seven days and extremely painful. She also had severe cramps in the legs. Two applications of radium were given, 75 mg., total twenty-four mg. hours.

Result.—Complete relief followed.

CASE 13 (61710)—*History*.—Miss M. A., T. N., aged 35, menstruated normally until ten months ago, when she began suffering great pain and having a profuse flow. She had had a decided loss of weight in the past ten months. Two applications of radium were given, one of 50 mg., with ten hours' exposure, and one of 75 mg., with ten hours' exposure.

Result.—Suppression of menstruation followed and great improvement.

CASE 14 (68655)—*History*.—Mrs. V. B., aged 38, had a normal menstruation at the age of 15 years, and had been married fifteen years, having one child, aged 11, and one miscarriage, seven years ago. Nine months ago an appendectomy and a myomectomy were performed on her. She had a scant menstruation, and felt dreadfully during the period, suffering general prostration. One application of radium of 50 mg. was given of 525 mg. hours.

Result.—Menstruation stopped for six months and then reappeared as the three day type, with no pain.

CASE 15 (55352)—*History*.—Mrs. H., aged 35, who had been married ten years, and concerning whom there is no record of menstrual history, was operated on two years ago for profuse menstruation, but without relief. She suffered intense headaches at the time of the flow, necessitating her remaining in bed. Two applications of radium of 75 mg. were given, with ten hours' exposure.

Result.—Suppression of menstruation and complete relief.

CASE 16 (56065)—*History*.—Mrs. E. T., aged 30, had been married eight years and had never suffered from menstrual periods before her marriage. She had been married two years when a child was born, and was healthy for two years after, when pains in the sides and ovaries developed during menstruation. The menstruation began to be irregular and to appear twice a month. The patient was cured one year ago for continuous bleeding, which was checked temporarily, but again appeared with the former pains. One application of radium of 75 mg. was given, with eighteen hours' exposure, a total of 1,350 mg. hours.

Result.—The flow gradually decreased. There have been no late reports.

CASE 17 (60803)—*History*.—Mrs. A. C., aged 32, who had menstruated normally and regularly until two years ago, had been married thirteen years and had had two children, the youngest aged 10. She had had no miscarriages. For the past two years the periods had been exceedingly painful and associated with nausea and intense headaches. Three applications of radium were given, two of 50 mg. and one of 75 mg., each with ten hours' exposure.

Result.—Complete relief followed.

CASE 18 (71289)—*History*.—Mrs. M. D., aged 46, who had been married twenty-seven years and had no pregnancies, and whose menstruation was, as a rule, irregular, was operated on five years ago, an appendectomy and the removal of one ovary and cyst being performed. After the operation the periods were regular, accompanied by a great deal of pain, requiring her to be bedridden for a week. For the past three years she had been menstruating every three weeks and for the past month the flow was very profuse, lasting from eleven days to two weeks. Four applications of radium of 50 mg. were given, with ten hours' exposure.

Result.—Complete suppression of the menses and complete relief followed.

GROUP 3. CHRONIC METRITIS

In this division falls the greatest number of cases. For want of a better term "chronic metritis" is used. Whether the pathologic condition is polypoid, hyper-

trophic or hyperplastic endometritis, or results from myopathic or vascular changes, most of these conditions are combined in the term "chronic metritis."

The ages of the patients are usually between 36 and 56 years. Many have had numbers of children; the uterus is in malposition, enlarged and firmer than normal, having associated therewith an enlarged chronic cervicitis. In these cases, bleeding is often rebellious; the patients may be curetted repeatedly, to no avail, and the final cure comes about through hysterectomy. Often the bleeding is so profuse that packing becomes necessary. To treat the condition, inflammatory diseases must be eliminated first; next, an exploratory curettage is performed in search of malignancy. Then, by the application of radium, the menstrual life is brought to a close. So far as our experience extends, it seems that the nerve upheaval is less through this method than the surgical. It is well known that most of these uteri have about completed the useful period, and when complicated by pathologic changes following a low grade infection, only complete removal gives the desired relief. Radium is unquestionably preferable in that it accomplishes the same result with less discomfort and no danger to life. As will be seen from the histories, thirty-five such cases were treated, with one partial failure. In this case there persisted an occasional bleeding, especially after coitus, and fearing potential malignancy, the uterus was removed.

There is some discomfort associated with radium intra-uterine applications, as seen in malaise, nausea and general lassitude, lasting from twenty-four to thirty-six hours; but this is negligible in most cases, and its worst form is in no way comparable to the operative course. If radium had no other field of virtue than is evidenced in this group, its use is warranted.

Though radium is by no means fully developed, and even if we discount some of the earlier claims for it, there have been produced sufficient positive data to cause it to take rank as a useful agent, and I feel that it should be made available to the localities through cooperating professional groups.

ILLUSTRATIVE CASES

CASE 19 (58300)—*History*.—A woman, aged 42, who menstruated at the age of 14 years, and whose flow continued regular and normal, had been married eighteen years. The oldest child was aged 16 and the youngest 11. For the past year menstruation had been very irregular and very profuse, lasting five days. At the last period there was a heavy flow lasting twelve days. Examination revealed a large uterus, freely movable. Two applications of radium were given, one of 75 mg. and the other of 50 mg., both with eleven hours' exposure.

Result.—Complete relief followed.

CASE 20 (6206)—*History*.—Mrs. H. S., aged 29, whose menstruation began when she was 16, and who has one child, aged 3, was cured two years ago and had the uterus suspended after the appendix removed. For a year and a half following she had a profuse flow during menstruation, and for the past two months the flow had been almost hemorrhagic, and accompanied with pain and large clots. She had pain in the back and the ovarian region, and lost weight and became constipated and anemic. Three applications of radium were given, each of 50 mg., with eleven hours' exposure.

Result.—Complete relief followed.

CASE 21 (61200)—*History*.—Mrs. L. T., aged 35, began menstruation at the age of 15 years, which was irregular and lasted eight days from the start. She had been married three months. The appendix was removed in September, 1915. Since the operation she had been bleeding twice a month. Menstruation was profuse and lasted from ten days to two

weeks. She was very weak from the loss of blood. Two applications of radium of 50 mg. each were given, with eleven hours' exposure.

Result.—Complete suppression of the menses followed.

CASE 22 (65485)—*History.*—Mrs. F. Y., aged 36, who had been married ten years and had one child, aged 9 (no miscarriages), had menstruation which was regular, but always painful. About a year ago the flow became more profuse and more painful. She was operated on in June, 1917, an appendectomy, a removal of the left ovary and a resection of the right ovary being performed. Six weeks after the operation she had a severe hemorrhage, necessitating packing. The uterus was large, freely movable and normal in position. The patient was a marked neurotic and definitely anemic, and was almost a physical wreck from the excessive bleeding. Four applications of radium were given, two of 75 mg. and two of 50 mg. each, with ten hours' exposure.

Result.—A complete suppression of menstruation and a complete transformation constitutionally followed.

CASE 23 (64525)—*History.*—Mrs. A. P., aged 40, had been bleeding profusely off and on for the preceding nine years, and an amputation of the cervix and a curettage were performed five years ago. She has seven children, the youngest aged 10. After the operation, the bleeding was more profuse, hemorrhagic at times. There were severe pains in the abdomen during menstruation. Four applications of radium of 50 mg. each were given, with ten hours' exposure.

Result.—Complete relief followed.

CASE 24 (73309)—*History.*—Mrs. W. R., aged 31, had had a profuse uterine bleeding for three weeks. She was curetted, Sept. 16, 1918. Relief followed for only two months, and then bleeding recurred. There was a slightly bloody discharge off and on, and the flow was very profuse at the time of her period. Three applications of radium of 50 mg. each were given, with ten hours' exposure.

Result.—Complete relief followed.

CASE 25 (56058)—*History.*—The patient, aged 38, began menstruation at the age of 14 years. The flow was regular but profuse. She had two children. For several years she had had frequent bleeding, both at the regular period and between the periods. Curettage relieved her for only two months. The bleeding stopped for ten days; then, September 13, the flow started and continued almost hemorrhagic, until November 9. One application of 75 mg. of radium was given, with twelve hours' exposure, 900 mg. hours.

Result.—There has been an improvement in bleeding, but it has not entirely stopped.

CASE 26 (61691)—*History.*—Mrs. A. J., aged 31, was perfectly healthy until four years ago, when her menstruation began to be irregular, very profuse, and to last five days. She was operated on one year ago. A dilatation and curettage and an appendectomy were performed, but no relief was obtained. The patient suffered loss in weight and became anemic. Four applications of radium were given, three of 50 mg. and one of 75 mg. each, with eleven hours' exposure.

Result.—The condition was relieved.

CASE 27 (65465)—*History.*—A woman, aged 42, began menstruation at the age of 17 years, which was regular and of five days' duration, and had had five full time children, the youngest of whom is aged 5. The patient was well until May 11, 1917, when she was awakened by a flooding which lasted ten hours. She had not flooded any more until two months ago. During the past two months she had had two hemorrhages, gradually growing worse. During this hemorrhage her temperature was as high as 103.5. Feb. 22, 1918, a dilatation and curettage was performed. Seventy-five mg. of radium were introduced at the time of operation, with nineteen hours' exposure, 1,425 mg. hours. March 13, 75 mg. were given, 900 mg. hours. The patient returned to the city a few months ago with a temperature of 102, whereupon a pyometra was discovered containing from 6 to 8 ounces of pus, which was drained.

Result.—The patient continued normal.

CASE 28 (73517)—*History.*—Mrs. O. W., aged 39, concerning whom there was nothing of interest in her early menstrual

life, was curetted three times for excessive bleeding, the last curettage being performed eleven years ago. She has one full term child, aged 16, and had one miscarriage eight years ago. Since this time she had had excessive bleeding. The flow had continued for five or six months and been very profuse at times. Three applications of radium were given, two of 50 mg. and one of 75 mg.

Result.—Complete cessation of the menses followed.

CASE 29 (56976)—*History.*—Mrs. M. C., aged 36, had had menorrhagia for the past four years. Three months ago she had a severe hemorrhage, and there had been an excessive flow for the past two months. One application of radium of 75 mg. was given, with twenty-four hours' exposure; four days later another, with twenty-two hours' exposure, and another with fifteen hours' exposure.

Result.—Complete cessation of the menses has followed.

CASE 30 (67828)—*History.*—Mrs. C. O., aged 40, who had had two children, the youngest of whom is aged 16, menstruated regularly until one year ago; she then began having flooding spells lasting from five to six days, and loss in weight. One application of 50 mg. of radium was given, with ten hours' exposure.

Result.—No return of bleeding; she was discharged relieved.

CASE 31 (73559)—*History.*—Mrs. S. C., aged 32, who had had four children, of whom the youngest is aged 4, had always had profuse bleeding during menstruation, but in the past four years it had increased in duration and in quantity. The patient was operated on a year ago; a cyst on the ovary was removed and a curettage performed. Since that time the bleeding has been more profuse and alarming, so that packing was the only means of control. She came to her physician to know if the uterus should be removed or if there was any other way that the alarming hemorrhage could be controlled. Three applications of radium were given, two of 75 mg. (one with ten hours' exposure and the other with twenty-four hours' exposure), and one of 50 mg., with ten hours' exposure.

Result.—Suppression of the menses and marked improvement constitutionally followed.

CASE 32 (57201)—*History.*—The patient, whose menstruation began when she was 15, and which was always regular until two years ago, had had five children, three of whom are living. Four years before the radium was applied, an amputation of the cervix and a curettage were performed for excessive bleeding and irregular menstruation. At the time of the operation the uterus was large and freely movable, and the amputation was performed with the hope that the uterus would diminish in size. The patient objected to removal of the uterus. Three applications of radium were given, of 100, 75 and 50 mg., with ten hours' exposure each.

Result.—The flow became slight, with spots after coitus. A hysterectomy was performed, but no malignancy found.

CASE 33 (56497)—*History.*—Mrs. P., aged 46, was in good health until six years ago, when she began to suffer with painful menstruation. Three years ago she began having an irregular flow, showing every three weeks and rather profuse. She was operated on one and one-half years ago for the removal of a polypus on the cervix. She also took roentgen-ray treatments. The flow reappeared six months later, hemorrhagic in character. One application of 75 mg. of radium was given, with ten hours' exposure.

Result.—Painful menstruation was entirely stopped and there has been no vaginal discharge.

CASE 34 (62617)—*History.*—Mrs. A. D., of whose case there is an incomplete history, was curetted unsuccessfully for excessive menstruation and profuse vaginal discharge. She was given an application of 25 mg. of radium, with twelve hours' exposure, with two large exposures.

Result.—Complete cessation of the menses followed.

CASE 35 (61640)—*History.*—Mrs. E. D., aged 41, whose menstruation began when she was aged 14, and was of the regular normal type, had been married nineteen years and had had two children, the oldest of whom was aged 16 and the youngest 11. She had had almost continuous uterine bleeding for the past year, very profuse at times and passing large clots. Amputation of the cervix was performed, June

30, 1917. Two applications of 50 mg. of radium, each with ten hours' exposure, were given.

Result.—Complete relief followed.

CASE 36 (65553)—History.—A woman, aged 42, who had been married twenty-one years, and has one child, aged 17, had been operated on six times for the repair of laceration and the removal of one ovary and tube. She had had fairly good health, only painful menstruation. Three months ago the menstruation began being irregular, appearing every fifteen days and lasting nine days. For the last six weeks she had been bleeding practically continuously, passing large clots. Three applications of 50 mg. of radium were given, each with ten hours' exposure.

Result.—Cessation of menses and complete relief followed.

CASE 37 (68847)—History.—Miss H. K., aged 40, the history of whose case is incomplete, had profuse vaginal bleeding. There had been previous local treatment without result. Three applications of 50 mg. of radium were given, each with ten hours' exposure.

Result.—Complete cessation of the menses followed.

CASE 38 (63434)—History.—Mrs. M. L., aged 51, who had had ten children, of whom the youngest is aged 8, was cured eight years ago for bleeding almost continuously, with a profuse flow. The menstruation was regular until twelve years ago, and since that time the patient had been bleeding in between the periods, the flow lasting from four to five days. Preceding the radium treatment, the bleeding was profuse and hemorrhagic in character. The vagina had to be packed to stop the flow. Two applications of radium were given, one of 50 mg., with eleven and one-half hours' exposure, and one of 75 mg., with eleven hours' exposure.

Result.—Complete cessation of the menses followed.

CASE 39 (66957)—History.—Mrs. E. A., aged 50, who had had six children, of whom the youngest is aged 14, had had no menstrual disturbance until four months ago, and since that time had been bleeding almost continuously with a profuse flow, at times hemorrhagic in character. She was quite anemic, and felt weak from the loss of blood. Two applications of radium were given, one of 75 mg., and one of 50 mg., each with ten hours' exposure.

Result.—Complete cessation of the menses followed.

CASE 40 (71749)—History.—Mrs. C. P., aged 53, who went through the menopause four years ago, a year later, from excitement and nervousness, had bleeding start again. There had been a slight flow, lasting one or two days, for the last year. Menstruancy was eliminated. Two applications of 50 mg. of radium were given, each with ten hours' exposure.

Result.—There was no evidence of bleeding.

CASE 41 (54768)—History.—A schoolteacher, aged 42, who began menstruation at the age of 14 years and was anemic, had no abnormal features of the flow until six years ago, when she developed an irregularity and hemorrhagia. The condition had gradually grown worse, and she had been bleeding for the last ninety-five days. The uterus was slightly enlarged, the adnexae negative. Two applications of 50 mg. of radium were given, each for twelve hours, and two of 75 mg., each ten hours.

Result.—Complete cessation of the menses, with a marked improvement of general health followed.

CASE 42 (57504)—History.—Mrs. M. L., aged 43, a healthy, robust person, had no menstrual disturbance until one year before the treatment, when the flow began to increase in duration, and a "spotting" and a "flooding" spell occurred in May, 1916. When the patient was examined, June 1, 1916, she had a profuse, bloody, vaginal discharge. The uterus was about the size of a double egg, symmetrical and freely movable. There was no pelvic trouble. Fifty mg. of radium were applied, June 5, with eleven and one-half hours' exposure, and 75 mg., June 20, with eleven hours' exposure.

Result.—The menses are now normal, and a complete cessation of the menses has followed.

CASE 43 (58620)—History.—Mrs. M. G., aged 40, who had been married twenty years and had three children, was operated on for complete laceration. For the past year the menstruation had been irregular and profuse in quantity, and

there had been continuous bleeding for the past eight months. The patient was anemic and very nervous, and had lost in weight. Three applications of radium were given, one of 75 mg. for eleven, and two of 50 mg. for ten and one-half hours.

Result.—There has been a suppression of the menses. Marked menopause symptoms were treated with hypodermic injections of corpus luteum.

CASE 44 (65956)—History.—Mrs. K. K., aged 42, who had been married seventeen years, and had four children, all living, the youngest of whom is aged 8, had been cured twice, the last time two years ago. The flow temporarily improved after curettage, but reappeared, quite profuse. For the past few months, the patient had been bleeding continuously, passing large clots. Three applications of radium, each of 50 mg., with eleven hours' exposure, were given.

Result.—The condition was completely relieved.

CASE 45 (70021)—History.—Mrs. B. L., the history of whose case is incomplete, began to have irregular menstruation ten years ago. For the past three or four months she had had flooding spells. She was cured two years ago and operated on twice since then, but the flow continued. Two applications of radium were given, each of 50 mg., and ten hours' exposure.

Result.—The condition was completely relieved.

CASE 46 (61565)—History.—Mrs. J. M., aged 39, who had had her last child four years ago, was well until two years ago, when she began bleeding excessively. Curettage gave temporary relief. For the past month she had had a continuous flow. She had lost in weight and was anemic. Six applications of radium were given: Aug. 8, 1917, 50 mg., twelve hours' exposure; August 15, 75 mg., twelve hours' exposure; September 3, 25 mg., eleven hours' exposure; November 27, 50 mg., eleven hours' exposure; Jan. 1, 1918, 50 mg., ten hours' exposure; and June 6, 50 mg., ten hours' exposure.

Result.—Complete relief followed.

CASE 47 (53807)—History.—Mrs. B. V. M., aged 38, of whose case there is an incomplete history, had a miscarriage four years ago. One month later excessive bleeding started, lasting four days. Every month she bled excessively, suffering with pains in the right side, the back and lower extremities. Three applications of radium were given, two of 50 mg. and one of 75 mg., each with eleven hours' exposure.

Result.—The excessive flow was controlled and the patient now menstruates normally, the menstruation lasting six days.

CASE 48 (58277)—History.—A woman, aged 30, suffered from profuse and prolonged menstruation. An appendectomy was performed and a cystic ovary and small polypus removed, Dec. 10, 1916. A practically continuous hemorrhage had persisted since the operation. Four treatments with radium, totaling 2,550 mg. hours, were given.

Result.—Suppression of the menses followed.

CASE 49 (50051)—History.—The patient, aged 45, had always had profuse menstruation, lasting for five or six days. The last few years she had menstruated twice in a month. The flow was copious. The patient had been treated locally for a long period. Two treatments with radium, totaling 2,675 mg. hours, were given.

Result.—The condition was completely relieved.

CASE 50 (57553)—History.—A woman, aged 35 years, had had flooding spells for several years, lasting five or six days. Blood appeared in large clots, and just previous to the radium treatment there was almost a continuous bloody discharge. The patient had been cured twice, and her appendix had been removed. She had had two courses of deep, roentgen-ray therapy, which checked the flow for a year, but it reappeared in hemorrhage form. One treatment with radium, of 550 mg. hours, was given.

Result.—Complete stoppage of menstruation followed.

CASE 51 (58801)—History.—A woman, aged 44, had been menstruating irregularly for the past year and a half. The flow was very profuse and returned every nineteen days, accompanied by pains in the back. One treatment with radium, of 800 mg. hours, was given.

Result.—Complete relief followed.

THE TREATMENT OF MYOMA UTERI
WITH RADIUM*

JOHN G. CLARK, M.D.

PHILADELPHIA

Sufficient time has now elapsed since my associates and I began the treatment of myomas and myopathic hemorrhages of the uterus with radium to arrive at a just estimate of its therapeutic value. Within certain limitations we may, with positive assurance, from our observation of more than 150 cases, assume that, from the standpoint of efficiency, safety and morbidity, this remedy must supplant surgical intervention in these tumors and for the relief of intractable myopathic hemorrhages. Beyond these limitations, however, we are also convinced that surgery still has a dominant place in the treatment of properly selected cases. Our experience of the last four years in the use of radium has, therefore, marked out rather well-defined lines of procedure, on which we may advance with safety. In any field of endeavor the danger of any innovation is that too much may be expected of it; likewise, too much is often claimed for it.

In our first experience we limited the use of radium to women within the menopausal cycle, and we have only gradually, and to a very limited extent, worked outside of this physiologic boundary, for we are convinced that in young women heedless radiation may be quite as unfortunate in its results as were the early efforts of overenthusiastic or poorly balanced ovariectomists. Radium is quite as potent in its power to bring on a premature menopause, and it is quite as upsetting to the nervous equilibrium of a young woman, as the removal of the ovaries. Fifty mg. of radium applied for twenty-four hours within the uterus of a young woman will in many instances bring on an abrupt and serious menopause; and while in our series of cases one or two patients have received this dosage, it was given in our earlier experience, when the potentialities of radium were not fully realized and its dosage was yet within the period of experimental endeavor. We quickly learned that a moderately prolonged intra-uterine application was most hazardous and not to be repeated. As we view this question, three essentials are capital in the use of radium; first, an accurate diagnosis in all cases; second, the proper selection of cases; and third, the careful graduation of dosage, beginning when young women are being treated, with a minimum application and increasing the duration of application slightly if the first attempt fails to check the excessive flow.

In our study of results in women within the menopausal years, certain facts stand out in relief. Among the most obvious are these: The tumor must be uncomplicated with coincident inflammatory disease; it must be causing hemorrhage, and it should not be too large. In our cases, when pain, even without coincident evidences of inflammatory disturbance, has been present, it is seldom relieved even though the tumor largely disappears; and in other instances in which there was an old salpingitis, a flare-up of a quiescent process has occurred. In two cases a subsequent operation was necessary—in one a hysterectomy and in the other a vaginal puncture of a large pelvic abscess was

necessary to relieve the patient. These two instances alone in our large series would not cast great discredit on this procedure, if all the other patients suffering with pain had been relieved of this symptom as the tumor decreased in size and menorrhagia ceased. Such, however, has not been the case; and we have, therefore, established a rigid rule that no patient suffering with pain lateral to the uterus is to be radiated. We choose an operation instead, for we can then ascertain the extent of the pathology and treat it conservatively or radically, according to the indications. In this connection we desire most emphatically to protest against the use of radium in the treatment of any acute or quiescent inflammatory case, whether associated with a myoma or standing alone. One of my esteemed colleagues, a radiologist, informs me that this point should be emphasized especially, for already an occasional enthusiast asserts that radium may be beneficial in the treatment of pyosalpinx. This degree of optimism is very dangerous, and cannot too quickly be discredited, for we have already observed its evil.

In keeping this remedy well within its proper bounds, its great value may be established without reflections on it; but through such a policy as that just referred to, its employment will be discredited. The proper selection of the tumor to be treated from the standpoint of size and symptomatology is also clearly necessary, for a therapeutic policy that covers all myomas regardless of structure is, as we view our experience, without justification. We have seldom used radium in a tumor larger than the size of a five months' pregnancy, and then only under very exceptional circumstances, such as in the presence of grave cardiac or renal complication or serious constitutional defects which plainly rendered any operation too dangerous. The rule which we generally follow is to confine this treatment to cases in which the tumors are the size of a three months' pregnancy or smaller. This policy is based on previous years of experience in the surgical treatment of myoma, which has established the great frequency of associated lesions in these large tumors, and we believe, therefore, that we serve a better end in recommending an operation in this class of cases than the application of radium.

One not infrequently finds in many cases a degree of anemia not accounted for by the loss of blood, and a complexion more like that of cachexia than occurs with an uncomplicated anemia; and furthermore, there is an asthenia of a toxic type which is not satisfactorily accounted for by a simple blood loss. Seldom is a malignant condition encountered, but not infrequently varying stages of degeneration of the tumors are discovered on macroscopic section marked by a grayish red or slaty discoloration of some of the tumors, indicating a partial gangrene, in others liquefaction necrosis, etc. Through the absorption of these necrotic or degenerating materials, serious inroads on the patient's constitution have occurred and a rapid healthful rebound follows a hysteromyectomy. Based on these observations, we cannot look with favor on the conversion of these large tumors through radiation into retrogressive tissues, which through absorption may cause toxic symptoms. Under such conditions the patient may serve as the sarcophagus for her decadent tumor. Also, these large tumors are very frequently associated with, or through pressure have produced, other lesions, especially of the inflammatory

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, June, 1919.

class. Frequently pressure symptoms have forced the patient to consult the surgeon, and there may be no variation of the menses from the normal. In such cases the tumor may be a pure fibroid, largely of a dense hyaline or calcareous type, certainly not responsive to radiation.

For these, and still other reasons, therefore, we find no evidence thus far in our experience to convince us that the large tumors should not be removed by approved surgical methods. In no instance has there been so quick a decrease in the size of even the smaller tumors to justify us in believing that the larger tumors which are giving pressure symptoms will diminish sufficiently rapidly in even six months or a year to give satisfactory relief. We stand, therefore, on the general principle against radiation in tumors larger than a three-month pregnancy, and in only the exceptional case do we deviate from this rule.

Those who decry the use of radium in all myoma cases ring the changes on the dangers of sarcoma. Such objections have no basis in fact, for seldom, indeed, is sarcoma a degenerative or concomitant evil of myoma. If it were as common as is asserted by some of these alarmists, out of every series of 100 partial hysterectomies, as are usually performed by American surgeons, a definite percentage of recurrent sarcomas in the cervical stump should be encountered. In more than 1,000 hysterectomies performed in the gynecologic department of the University Hospital such a sequel has been observed but once. In a review of 816 myomas in our laboratory by my associate, Dr. Charles C. Norris, he finds only thirteen sarcomas, or less than 0.1 per cent., which were not diagnosed at the time of operation, only twenty-six such cases in all this series having been encountered. Based both on clinical and on laboratory conclusions, therefore, we deal with fears solely within the domain of fallacious supposition in discussing the dangers of sarcomatous changes in myomas and fibromas. Even were these fears justified, there would still be no strong argument against the use of radium, since these tumors quickly react to this influence. It is not, therefore, the fear of sarcomatous degeneration which makes us slow to radiate large tumors, but it is because of the other objections just enumerated. To define our policy clearly, we would say that we radiate chiefly for one symptom, and that is hemorrhage. In myopathic changes in the uterus and in the smaller myomas causing excessive flow a safer or more certain means of relieving this symptom has not been found, for it acts with clocklike regularity, and we therefore consider a small myomatous uterus causing menorrhagia in a middle aged woman as no longer within the surgical domain. When radium is not available, the use of the roentgen ray in skilled hands may take its place. In the near future, therefore, we believe that the surgeon who operates in this type of cases will have a difficult task ahead of him in justifying his action.

SYMPTOMS ACCOMPANYING RADIATION

Under special headings may be enumerated some of the occasional symptoms accompanying radiation:

Nausea.—Frequently within from twenty-four to forty-eight hours after the intra-uterine application of radium the patient will experience considerable nausea, not, however, greater than that observed after the administration of one-fourth grain of morphin in the occasional case. As we always perform a dilatation

and curettage under nitrous oxid anesthesia, with a preliminary one-fourth grain of morphin administered one hour before the anesthetization, we have often felt that there were about equal chances between the effects of the radium and the morphin in the production of the symptoms; for nausea and vomiting are the exception rather than the rule after radiation. In no case has this symptom been either alarming or persistent.

Pain.—This symptom is also a variable factor, and may be attributable to the curettage, which is performed in all of these cases for diagnostic assurance. When this symptom persists or is accompanied by fever, we fear the possibilities of an acute inflammatory attack or the exacerbation of a quiescent lesion. This complication has occurred but seldom. However, it has been noted in possibly twenty or thirty instances in our series, and we are inclined to adopt in the future the plan of merely dilating the cervix and inserting the radium in those cases of periodic menorrhagias following a cyclic menstrual type without intermenstrual spotting; for in no instance have we discovered a carcinoma of the fundus in any of these cases, notwithstanding a careful routine study of the curettings. In those cases, however, in which there is intermenstrual spotting, or in which there is continuous bleeding, curettage should never be omitted, for this is the court of final diagnostic resort. When this very suggestive symptom has been present, carcinoma of the fundus has occasionally been encountered and an immediate or subsequent hysterectomy has been performed. A simple hysterectomy carries so high a percentage of cures in this class of cases that we never trust to radium, but invariably choose the more radical surgical measure.

Leukorrhœa.—The rule in all of our cases has been that a yellowish but never profuse leukorrhœa will follow radiation for a short time—usually from three to six weeks. Hemorrhage likewise may not cease at once, although this is the rule. We warn our patients against apprehension if the flow does not cease at once, and usually tell them to expect no decided result under six weeks, although the great majority are relieved at once of excessive bleeding, but have a somewhat yellowish, sticky discharge for possibly six weeks, after which it ceases. In several instances a profuse leukorrhœa has actually been cured by radiation.

Menopause.—The change of life in these cases varies in its phases, as the constitutional and temperamental characteristics of women vary. In this connection one might employ the lines of the comic opera librettist: "There are never two women alike, and never one woman alike twice." In the more marked grades of anemia we believe the climacteric change is more abrupt and attended with more pronounced symptoms. This may be explained on the theory that the hematogenous system has been working for weeks or months at a great speed in corpuscular generation, since the continuous loss of blood is so great that this excessive deficit must be remedied. A quick check on this great activity must in many instances jar the physiologic equilibrium and thus induce a more acute menopause. So far as we are able to judge, we believe that the menopause is somewhat more trying to the average woman under an abrupt cessation than when she drifts into this change more naturally. In estimating the possible objections to radiation this symptom may possibly be classed in this light, although it in no

way differs from the same sequel after a hysterectomy in which the ovaries are removed. In general, we find our patients very enthusiastic over their results, and count this possibly trying symptom as of light moment compared with their satisfaction over an escape from an operation.

FAILURE TO RELIEVE

In four cases we have failed to relieve patients sufficiently to satisfy them or ourselves, and we have subsequently resorted to a hysterectomy. Two patients have been operated on in other clinics. So far as we have observed, no disadvantage has occurred from the preliminary radiation, as all of the patients on whom an operation has been performed have recovered without complication.

TECHNIC OF APPLICATION

In our entire series of cases we have varied but little in our method of treatment. For women in the menopausal years, one extra-uterine application of 50 mg. of twenty-four hours' duration is made. Under gas the cervix is dilated and a simple curettage for diagnostic purposes is performed, followed by a light packing of the uterine cavity with a 5 per cent. solution of iodine momentarily before the radium is introduced. We enclose the platinum or silver radium container in a black rubber drainage tubing securely tied at each end. A 50 mg. tube is inserted into the fundal cavity to the top and left thus for twenty-four hours. When the cavity is $3\frac{1}{2}$ inches or more in depth, we usually use 25 mg. tubes arranged in the rubber tubing tandem fashion, to insure a wider radiation of the uterine wall. After the radium is withdrawn, we usually keep the patient in bed three days, as after ordinary curettage, and at the end of five days she is discharged and permitted to resume her ordinary duties.

In women under 40 years of age we grade the dosage largely according to their years. As a rule, if the menorrhagia is excessive we may leave the tube in place twelve hours if the patient is over 35. In still younger women we never apply it more than six hours, choosing rather to make a reapplication several weeks later if the first fails. In this way the menopause will not be induced. There are several instances in our series in which normal menses have occurred after an interval of weeks or months, even when a twenty-four hour dosage has been applied; but as a rule the menopause is permanent.

RESULTS

In one phenomenal case, that of a woman aged 32, married ten years and sterile, who had suffered from severe menorrhagia which had reduced her hemoglobin below 35 per cent., the flow ceased quite abruptly and she passed through a rather severe menopausal period and yet became pregnant and went to term; but through a severe postpartum hemorrhage the poor woman lost her life. In many instances patients have passed through a typical climacterium, and the periods have returned and have then resumed a normal menstrual physiology. This phenomenon has been sufficiently frequent to make us believe that the radioactivity of the usual dosage is expended chiefly within the uterus and not on the ovaries. In considering the amount of radium employed in these cases, we feel that the smaller dosage, such as we have indicated, has given very satisfactory results, and, therefore, it is within the easy range of every well equipped hospital

to have available at least 100 mg. of this substance for use in their clinical departments. It should, however, be placed within the jurisdiction of one capable clinician of the staff to advise as to its use. Certainly it is not a remedy for haphazard use, for it requires the training and judgment of a skilled specialist to advise as to when and how it should be applied.

ABSTRACT OF DISCUSSION

OF PATERN OF DR. S. M. D. CLARK AND JOHN G. CLARK

DR. HAROLD BAILEY, New York: In the radium treatment of cervical cancer there are two problems: The application of the radium to the cervix in such an amount that there will be a retrogression of the local lesion without the production of deep slough or fistula, and the radiation of the parametrium by such massive dosage that the necessary amount of ray intensity (whatever that may be) will reach all parts of the pelvic tissue involved. The first problem is comparatively simple from the point of physical conditions, for the cervical canal is approximately in the center of the involved part and offers an ideal location for an applicator in the shape of a capsule. This type of application will probably always be the chief or most important single factor in the treatment. Granting that a complete retrogression is produced in the cervix, then we are in the same position as if the cervix and uterus had been removed by a simple hysterectomy and the return of the disease is just as certain as if this operation had been done. With small amounts of radium the only way so far as I know, of producing distant effects in the parametrium, excluding rectal application, is by reapplication of the capsule to the same areas in the cervical canal. Experience through nearly two years of use of radium in this manner has convinced me that it is seldom effective and furthermore that it produces lesions which are quite important as regards the patient's comfort. The second problem is best solved by two types of accessory applications that require large amounts of radium, amounts in the magnitude of a gram. Properly protected these large doses may be played for short periods in the posterior fornix at either side of the cervix and thus radiate the lower part of the broad ligament. Amounts of 1 gm. may be placed above the surface of the skin and over different areas in turn and thus conduct an additional radium intensity into the pelvic tissues. In this manner it is highly probable that sufficient radium intensity can be produced throughout the pelvis to affect unfavorably any cancer cells that may happen to be there. Unfortunately just the amount that will accomplish our purpose without producing an endarteritis that will some months in the future cause a sclerosis with stricture and fistula and other serious symptoms, must be arrived at by careful experiment. Therefore, it is quite patent that the posse of small amounts of radium must be satisfied at present to conduct palliative treatment of inoperable cancer and should not attempt to treat operable cancer. The preoperative treatment of cervical cancer with radium should consist (where only small amounts are available) in using the intracervical capsule for a considerable dose and then waiting three or four weeks before operating. Caution must be used in considering too favorably the temporary healing of the local lesion for the common history of these cases is that within the period of a year further cancerous development ensues. In cancer of the body of the uterus operation should be done following radium. Under radium treatment small fibroids may retrogress so that their size causes no symptoms. Larger fibroids may diminish in size but there remains above the true pelvis a heavy sclerotic mass that is apt to cause symptoms from its weight alone. The bleeding in most of the cases may be checked entirely. Cessation of menstruation is probably caused by the lack of functional activity of the ovary and the endarteritis produced in the tumor itself. In selecting the cases it is necessary to rule out not only all those with abnormal conditions in the pelvis but also all very large or the pedunculated or adherent or submucous fibroids and also all those with large retrocervical nodules. There remain suitable for the

radium treatment all those that have some physical condition rendering operation inadvisable and also all small freely movable fibroids without any discernible complications. This last mentioned group should have the radium treatment as a tentative measure. The mortality from radium treatment of fibromyoma together with that of the undiagnosed and untreated complications may be higher than 1.5 to 2 per cent. Radium is particularly successful in the treatment of this class of cases. As in the fibroid group the bleeding does not cease usually unless the menstruation is stopped. Care must be used in selecting these cases. A thorough curettage should be done and all the scrapings examined. One piece may show adenomatoid membrane and a nearby section may show signs of beginning cancer. Another possibility that deserves consideration in the radium treatment of younger patients is that a partially ripe ovum may be so injured that on impregnation later abnormal development may occur.

Dr. ERNEST C. SAMUEL, New Orleans: We have not attempted to radiate tumors that are large or rapidly growing, impacted in the pelvis, causing pain or pressure symptoms. We have done this only when they were of small size and in patients beyond 35 years of age. The tumors not causing hemorrhage have been left to the surgeon, except in probably one or two instances. I was glad to hear what Dr. Clark said concerning sarcoma being a bugbear in the matter of radium treatment. We have had some pain following the application of radium, but since we have ceased using morphin preliminarily to radium the nausea has been reduced at least 75 per cent. We have given up entirely the use of gas for the introduction of radium. Of the 125 patients treated three have come to operation. In one case there was no result whatever from very large doses frequently repeated. As Dr. Clark said, after very careful examination there was no evidence of malignancy found in the specimen. I have had three unhappy experiences with a lighting up of infection after radium was used. I cannot agree with Dr. Clark as to the menopause being a bit short. Our observation has been different. It seems to come on a little more slowly and not to produce the symptoms as fast as he has observed. In regard to malignancy, we are not using the very large dosage of which Dr. Bailey speaks. We have absolutely discarded it, using only the smallest dosage, and after three treatments, which I think is a little more than Dr. Clark gives, if there is no appreciable effect on the mass, we stop treatment entirely and tell the patient's family that nothing more can be expected of radium. Dr. Schmitz of Chicago has demonstrated that implanting the radium tube in the parametrium is of much value. It seems to offer much in the future care of these cases, especially in recurrences out in the parametrium and deep in the pelvis.

Dr. A. H. CROVER, Chicago: Of the patients when we have treated with radium we have available statistics from 220. Forty-six with uterine cancer have obtained some palliative relief. Of this number there has been very marked amelioration of the symptoms in fourteen. Up to the present we have had no patient in whom we anticipate that a permanent cure has been secured. The hemorrhage ceases, the discharge stops, the cervix almost invariably heals over; there is cessation of pain for several months, but eventually the patient succumbs to the disease. In the protection of the bladder and the rectum we have found that, instead of the use of the customary gauze pack, insertion of a rubber dam is very much more satisfactory. Because of its elasticity it can be inserted without distress, the parts are forced away from the carcinomatous tissue and we have absolutely no trouble from adhesive vaginitis. In cases in which it is desirable to use radium as a preliminary to operation I think it is well either to operate within the first twenty-four hours before inflammatory reaction has occurred, or to wait for two and a half or three weeks in order that an immunity may have been established from the inflammatory reaction following the application of radium. In the noncarcinomatous group of cases, without doubt radium is of great therapeutic value. We are able to effect a cure in almost all cases where radium is indicated. We have found that the routine use of 1,200 mg. in small sized

fibroids and with patients in the menopause there is a tendency to hot flushes which disturb an otherwise excellent result. On this account we are inclined to use a smaller dosage and have recently employed 1,000 mg. or less. In severe hemorrhage in women of younger age, the so-called idiopathic hemorrhage, even a smaller dosage will suffice. In all of these nonmalignant cases there is apt to be bleeding for several weeks, sometimes for a couple of months, but almost always a cure is assured if we are patient. Another complication is that of a very profuse watery discharge, persisting oftentimes for three or four months; but I know of no case in which it has not spontaneously ceased. I am optimistic concerning the use of radium in intractable leukorrhea of cervical origin. The cervix is open to infection from below. As a result there is marked hypertrophy of the cervical tissues, which are permeated with infection by all sorts of organisms. Fifty milligrams of radium are inserted in the cervix as high as the internal os and left for twelve to sixteen hours. Its use is sometimes necessary again after two months. But finally the glands are destroyed and the infection ceases. The ultimate results are extremely gratifying.

Dr. EDWARD H. RICHARDSON, Baltimore: I am glad to note that the general tone of these papers has been conservative. There is no longer any doubt about the superiority of radium over other methods of treating certain cases of myoma and I believe the specific indications for its use will soon be defined accurately through the splendid work now being carried on in this field by those possessing this agent. In general, I agree with the limitations as outlined by Dr. John G. Clark. There is one group to be kept in mind, however, which he may have mentioned. This is illustrated by a case of a myomatus uterus not larger than a four months pregnancy in which I advised operation. The ovaries could not be palpated prior to laparotomy and when they were exposed, the left one was found to be moderately enlarged from cystic degeneration while at one point on its surface there was a papillomatous outgrowth, one and one-half centimeters in diameter, which appeared to be carcinomatous in nature. One must be careful to eliminate such early cases of carcinoma of the ovaries as a complication of myoma before advising radium, because, if I am informed correctly, it has been the uniform experience of radiologists that malignant growths of the ovaries are not amenable to this form of therapy. With reference to the treatment of carcinoma of the cervix and of the body of the uterus by radium, my observations have been limited to a small series of cases, all either hopelessly inoperable or instances of intrapelvic recurrence. Under such circumstances a cure could not reasonably be expected, but in all of them the rate of growth seemed to have been materially retarded and in other respects, too, its superiority as a palliative measure in these hopeless cases was convincingly shown. It is quite possible that further improvement in the technical methods of radiotherapy may yet reward by brilliant achievement the efforts of those now courageously working in this discouraging field. In the meantime they should receive the untainted courage and encouragement of the profession.

Dr. LE ROY BROOK, New York: It would be a great mistake to allow the impression to go out from this meeting that we may indiscriminately make use of radium or the roentgen ray in the treatment of fibroid tumors, and I am glad of this opportunity to accentuate the limitations placed on the treatment of fibroid tumors as Dr. Clark of Philadelphia has done. He clearly brings out the point that the essential factor is a positive diagnosis that there are no complications and the other that of hemorrhage. The presence of pain indicates that some intercurrent pathologic condition exists, such as associated disease of the ovaries and tubes with adhesions or changes in the tumor growth. In 1,700 consecutive cases of fibroid tumors in which operation was done, the following changes had taken place in the tumors: In ninety cases there were necrotic changes; in twenty-five cases there was calcareous degeneration and in twenty-five cases there was malignant disease of the fundus—not of the cervix. In other words, in 8 per cent. of the fibroid tumors conditions existed in which radium should not be used and in which, as a rule, no knowledge of such changes could be diagnosed prior to the

operation. There were a number of ovarian complications, 3 per cent, contraindicating the use of radium. These included ovarian cysts, dermoids and malignant disease. In 7 per cent, there was an infectious salpingitis, not salpingitis the result of increased circulation associated with fibroid tumors. This is where the danger arises in the use of radium—in our inability to make a positive diagnosis and to exclude the intercurrent pathologic condition. In a clear case, however, with absence of coincident pathologic conditions, or of degenerative changes in the fibroid tumor growth, radium is unquestionably of the greatest possible assistance. By it we can control hemorrhagic symptoms in uncomplicated fibroids and save the patient from a mutilating operation. I am glad to place this emphasis on the limitations in the use of radium which Dr. Clark has brought out.

DR. JOHN OSBORN POLAK, Brooklyn: Diagnosis is the keynote. All have defined the class of cases in which radium should be used, but they have not shown us how to make this diagnosis. Dr. Clark of New Orleans says they have discarded the use of morphin and of anesthesia, in the introduction of the radium, but he does not tell us how he makes a definite diagnosis as to the absence of inflammatory adnexal conditions without the use of anesthesia. Of course, histories are almost always reliable, but errors occur in the best regulated hospital. We recently had two cases in which we used radium; a very active reaction resulted. Both tubes and ovaries had been removed for inflammatory conditions. The operating surgeon had left a large myriotic uterus which was causing hemorrhage. Both these women were suffering from diabetic trouble and operative intervention was inadvisable. Both patients were cured with radium but the introduction of radium into these uteri caused the most active inflammatory reaction in the parametrium and in the peritoneum. Our own experience with radium has been limited to these cases of enteritis or subinvolution near the menopause with hemorrhage. We have had seventy-six cases treated for hemorrhage with absolute cure of the bleeding in all of the cases. Three patients have had to have repeated exposures. There has been only one case of a young girl in which radium was used for the control of hemorrhage. This case was treated by repeated small applications of radium with a most satisfactory result. I think it is a mistake for us to give the impression that operation for fibroids is to be eliminated. In watching the cases of other men in which large doses of radium have been used for the control of tumors I have been very much interested in seeing that a number of these cases had subsequently to be operated because of pressure changes and lack of diminution in size. The hemorrhage, however, in all cases in which I have seen radium used and in all the cases in which we have used it ourselves, has been absolutely controlled.

DR. HENRY SCHMITZ, Chicago: We have endeavored to find an explanation of the fact that some myomas disappear following radium application while others do not. In the latter instance the microscopic sections invariably show the presence of numerous atrophic fibroblasts and an abundance of highly differentiated fibrous tissue. In myoma uteri the dosage has been reduced greatly in the last two years in our work and we now deem a single application of 25 to 35 mg. for twenty hours sufficient to bring about amenorrhea. If the patient fails to respond to one such application we may repeat the dose after three or four months, when the desired result will be obtained. Such a careful plan of treatment prevents the later appearance of profuse leukorrhea of which so many patients complain and which at times seems to be quite persistent, lasting not only three to six months, but sometimes even a year. Concerning the use of radium in carcinoma of the uterus we must always remember that if it did nothing else than give relief it is preferable to the canterly in inoperable cases. In the hemorrhagic myopathies the results of radium therapy have been good, provided the causative factor has been corrected first. It is of special importance to rule out malignancy. Of twenty-three inoperable cases of cancer treated in 1914 three patients are living and well today, hav-

ing had no recurrence. The demonstrable reduction in the size of the tumor of a kind not to be attributed to the natural processes of evolution of that tumor or its associated lesions is the one essential feature to be observed in speaking of a curative action of any agent. On the other hand, if such a therapeutic measure relieves symptoms such as hemorrhage and discharge and brings about local healing, the agent is only a palliative one. If we consider the results of radium therapy from this point of view we shall avoid many misunderstandings or wrong conclusions.

DR. SAMUEL M. D. CLARK, New Orleans: If the case histories are studied it will be seen that most of the patients had previously been operated on in some fashion. As to the fibromyomas, I was interested to hear of the percentage of a 'neal inflammation being so low, not over 30 per cent. In the colored women, among whom myomas are common, a 'neal inflammation is found in 87 per cent, having only 15 per cent, suitable for radium treatment. It is to be regretted that there was not more discussion on the control of menstrual bleeding in young women without producing suppression. We need more light on this phase of the subject.

DR. JOHN G. CLARK, Philadelphia: So far as my attitude toward radium is concerned, therapeutically it is at most a mere handmaiden of surgery. As I have stated in my paper, there are cases of fibroid which should not be treated by radium, thus reducing the total number of cases to which radium is applicable to a smaller proportion than those submitted to surgery. Particular stress should be laid on the necessity for all of these cases to have the best diagnostic advice before the determination to use radium or the roentgen ray is arrived at. Certainly, it is not within the province of the roentgenologists to pass on this phase of the question. Unless this decision is carefully controlled, serious opprobrium will be cast on a very valuable remedy. Dr. Samuels believes that his patients have not suffered as much with acute menopausal symptoms as ours have. Possibly this may be due to the fact that he has used a smaller dosage. At least, this is the only way in which I can explain the apparent difference in our results. So far as the question of leukorrhea is concerned his patients appear to have a slight leukorrhea but like our series, this is never annoying. seldom are they troubled with this slight discharge for more than six weeks, and in many instances not at all. A very gratifying sequel in several cases of chronic leukorrhea has been a cure by the use of radium. The one point on which special stress should be laid is that radium does not take the place of surgery, except in a limited number of cases. Every surgeon here knows how reluctantly he advises a hysterectomy in a woman in the menopausal years who is suffering with mere myopathic hemorrhage or from a very small fibroid, as the gravity of the operation is greatly out of proportion to the lesion. These are the cases par excellence for the use of radium and they should never be submitted to operation.

Health Centers.—A health center is a place where people may come to learn how to keep well. It is not a convenience for any community with a population of 1000. A health center is simply itself, a single room, if no more is available, in the central part of the town, where the public health nurse and doctor in attendance can give advice to people on matters of health. This health center should be owned by the board of health of the municipality, as it is really a municipal duty to see that the health of the citizen is preserved. Very often, however, it is more easily started by some private philanthropic agency, the Visiting Nurse Association, for example, could carry it along as a department, until it is finally taken over by the municipality. Such a health center need not be confined to any particular age group. Prenatal instruction can be given there; the young can be supervised there; it can serve also as a community center for the child of preschool age, the school child, the child in industry, and, for that matter, the adult. Every community, or group of communities, should have one.—*Public Health* 6:120 (May-June), 1919.

TREATMENT OF EXTRA-UTERINE PREGNANCY AFTER THE FIFTH MONTH*

ALFRED C. BECK, M.D.

BROOKLYN

The incentive for this study was a case of full term extra-uterine pregnancy which I had the good fortune to treat in the Long Island College Hospital last fall:

Mrs. C. C., aged 32, primipara, married nine years, menstruated regularly every twenty-eight days. Her last menstruation began Jan. 18, 1918, and continued for three days. No bloody vaginal discharge was noticed at any time during the pregnancy prior to the day before admission to the hospital. In the second month, the patient suffered from pain in the right lower quadrant of the abdomen. Occasionally, this was severe enough to necessitate her remaining in bed, but at no time required the services of her physician. After about two weeks, the pain disappeared, and she resumed her usual household duties. No further symptoms were observed until the last month, when the fetal movements became very active and painful. Oct. 4, 1918, intermittent pains and a bloody vaginal discharge led the patient to believe that she was in labor, and a midwife was called. After two days of suffering, the patient was brought to the hospital. On admission, examination revealed a marked distention of the abdomen. The fetal head was felt very close to the examining fingers in the left lower quadrant. Neither contractions nor the round ligaments could be palpated. Percussion revealed an irregular area of tympany, which extended from the ensiform to slightly below the umbilicus. The fetal heart was heard on the right side below the umbilicus. From these atypical abdominal findings, the fetus was thought to be free in the abdomen.

Because of the extreme distention, it was deemed advisable to postpone operation until after an attempt was made to relieve this complication, as the patient was otherwise in good condition. Gastric lavage and colonic irrigations were used to good advantage, and on the following morning, Oct. 8, 1918, the patient was prepared for a laparotomy.

Vaginal examination under anesthesia disclosed a soft thick cervix, which admitted two fingers easily. The uterus was distinctly felt on the right side and was about the size of a four months' pregnancy. Digital exploration of its cavity revealed it to be empty, and the walls were found to be free from rupture.

The abdominal was opened through a midline incision which extended from the symphysis to the umbilicus. After the sac had been incised, a well developed child was extracted. The placenta was found to be widely attached to the right broad ligament and sigmoid and extended anteriorly along the peritoneal peritoneum almost to the midline. By the use of clamps and ligatures the placenta was removed. A vigorous

hemorrhage now took place from the friable areas through which some of the ligatures had torn. Pressure was made over the abdominal aorta, thus partially arresting the flow of blood, while the bleeding points were secured with three clamps. These were surrounded by a Mikulicz drain, and the wound was closed, except in its lower angle, through which the drain and clamps protruded. The patient was returned to her bed in good condition. The duration of the operation was forty minutes.

The clamps were removed on the third day, and the drain was started on the following morning. The temperature rose to 100.6 on the second day following the operation, after which it remained below 100 until October 20, when the wound suppurated. A febrile convalescence continued for twenty-four days, during which the highest temperature was 102.4. The patient was allowed out of bed, Nov. 23, 1918, and was discharged from the hospital in good condition three weeks later.

She has returned several times during the past five months to the post partum clinic, where examinations have shown a complete recovery.

The child was 50 cm. long and weighed 3,450 gm. at birth. No malformations were noted. It was placed under the supervision of Dr. Watton of the department of pediatrics, who recommended artificial feeding because of the mother's condition. On the eighth day, suppurative parotitis developed. Following recovery from this condition, the child did well and weighed 15 pounds and 10 ounces when last seen, June 10, 1919.

RECORDS OF TWO HUNDRED AND SIXTY-TWO CASES

The treatment of this condition must be learned from a statistical analysis of the results in a large series of cases, since the experience of individual operators is so limited that their conclusions are less satisfactory than the deductions which one might make from a collective study of the cases reported in the literature. A careful search of the literature, as well as replies to a

questionnaire which was sent to over 200 obstetricians, revealed only 262 cases of extra-uterine pregnancy between the years 1800 and 1919 in which operations were performed after the fifth month, with a living fetus.

MATERNAL MORTALITY

Table 1 shows the maternal mortality following operative treatment.

A. Prior to 1800, that is, before the days of asepsis, fifty patients were operated on for this condition, and thirty-four died, a mortality of 68 per cent.

B. During the following ten years, 35.3 per cent. of the patients died. As suggested by Harris, this improvement probably was due to the influence of the teaching of asepsis.

C. The mortality was further lowered in the succeeding ten years to 21.9 per cent. of ninety-one cases, as a result of the advances made in the technique of abdominal surgery.

D. Only twenty-two case reports were found in the literature of the past nine years, owing to the fact that the war

Chart 1.—Cases in which patients were moribund at the time of operation.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Sixty-ninth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

greatly interfered with the collection of medical data. Of these twenty-two patients, four died, a mortality of 18.1 per cent.

E. The mortality for the entire series of 262 cases was 35.8 per cent.

OPERATIVE TREATMENT

In spite of this high death rate (35.8 per cent.), the treatment of advanced extra-uterine pregnancy always

1. The best time to operate is during the sixth or the seventh month.

2. The added risk in waiting for a well developed child is slight up to the thirty-ninth week.

3. The danger of a catastrophe is sufficiently great in the last two weeks to warrant interference before this period is reached.

OPERATIVE RISK AT THE VARIOUS PERIODS OF GESTATION

The operative risk at the various periods of gestation is shown in Chart 2. The danger from the operation itself increases as pregnancy advances, until the last month is reached, when it is less than at any previous time. An analysis of all of the deaths shows the apparent reason for this diminished risk during the tenth month to be a lessened tendency toward hemorrhage at that time. After the thirty-eighth week, 36.8 per cent. of the deaths were due to hemorrhage, while almost twice as large a proportion, 65.3 per cent., resulted from this cause when the operation was performed before the last two weeks.

By adding the moribund cases in Chart 1 to the operative deaths in Chart 2, the maternal mortality is found to be 30 per cent. for the sixth month, 33 per cent. for the seventh, 37 per cent. for the eighth, 45 per cent. for the ninth and 32.8 per cent. for the tenth. Chart 3 is a graphic representation of these figures, and illustrates the fact that, even though almost 10 per cent. of the patients operated on during the last month were moribund before the operation, the gross maternal mortality for the tenth month is almost as low as in the sixth, and lower than in the intervening months.

Chart 2.—Operative mortality at different periods of gestation.

should be operative, as noninterference gives even worse results.

Time to Operate.—Our decision as to the proper time to operate depends on three factors:

1. The danger to the mother of waiting for a viable child.
2. The operative risk at various periods of gestation.
3. The best time to interfere in the interest of the child.

DANGER TO THE MOTHER OF WAITING FOR A VIABLE CHILD

The danger to the mother of waiting for a viable child is shown in Chart 1. From a period of relative

TABLE 1—MATERNAL MORTALITY

Period	Cases, No.	Deaths, No.	Mortality, per Cent.
A. 1891 to 1900.....	50	31	62.0
B. 1901 to 1910.....	99	15	15.3
C. 1911 to 1920.....	34	10	29.4
D. 1921 to 1929.....	22	4	18.1

quiescence during the sixth and seventh months, the maternal risk gradually but slightly increases in the eighth and ninth, to become a prominent factor in the tenth month. Twelve of the 122 patients who reached the last month were moribund before the operation was performed. Of these moribund cases, only two were noted during the first two weeks of this five-month period, while ten occurred during the thirty-ninth and the fortieth weeks. Were this growing danger in the late stage of pregnancy the only factor to be considered in determining the time to operate, we might conclude that:

Chart 3.—Mortality at different periods of gestation.

BEST TIME TO INTERFERE IN THE INTEREST OF THE CHILD

The most suitable period for intervention in the interest of the child is shown in Table 2, which gives the duration of life of the infants born at different periods. These figures are very conservative, as many of the children reported as living at the end of from two to four weeks undoubtedly lived longer. Since

56.6 per cent. of the sixty infants born at from thirty-six to thirty-eight weeks survived one month, while only 47.5 per cent. of the eighty born in the thirty-ninth and fortieth weeks lived the same length of time, it would seem that the safest time to operate in the interest of the child is in the thirty-eighth week.

If the series of cases is sufficiently large to permit us to draw conclusions we may infer that:

1. The best time to operate is in the thirty-eighth week.
2. We are justified in waiting for this period of election, provided the patient is kept under observation.
3. This plan will best conserve the interests of both mother and child.

OPERATIVE TECHNIC

The difficulties which one meets in operating in these cases are usually encountered in the handling of the placenta. Its removal frequently has resulted in uncontrollable hemorrhage. The opposite procedure, its retention within the abdomen, is said to have been responsible for many cases of fatal sepsis. Table 3 gives a comparison of the results obtained by each method.

Before asepsis was generally practiced, the customary routine was to leave the placenta and drain

TABLE 2.—INFANT MORTALITY *

* In 262 cases, in which the period of gestation was from twenty-eight to forty weeks, eighty infants survived one month, 30.6 per cent. In eighty cases, in which the period was from thirty-nine to forty weeks, thirty-eight infants survived one month, 47.5 per cent. In 146 cases, in which the period was from thirty-six to forty weeks, seventy-two infants survived one month, 50.4 per cent. In sixty cases, in which the period was from thirty-six to thirty-eight weeks, thirty-four infants survived one month, 56.6 per cent.

until it came away. Since 1890, most operators have preferred its removal whenever possible. The more frequent use of the latter plan has led to marked improvements in its technic and a consequent progressive diminution in the mortality, while little change has been noted in the results following marsupialization. When the placenta was left, the usual practice was to suture the sac to the abdominal wound and drain until its contents came away. These patients frequently became infected, and many died of sepsis. As the removal of the placenta is impossible in some instances, our results might be bettered if we used the modern surgical principle of avoiding drainage in these cases. We leave blood clots and placental tissue in the abdomen without drainage when we operate on earlier extra-uterine pregnancies. Would it not be well to follow the same routine when it is impossible to remove the placenta in the advanced cases?

With this suggestion in mind, I placed three fifths of a 500-gram placenta, removed by cesarean section, in the abdomen of a dog. The animal promptly recovered. Two months later its abdomen was reopened,

and no trace of the placenta could be found. Absorption takes place under similar conditions in the human being, as has been demonstrated by eight of the cases included in this analysis. The placenta was left to be absorbed in the abdomen in twelve patients. Four of these died, a mortality of 33.3 per cent. In two of the fatal cases, death occurred from sepsis on the second and fourth days and, in all probability, was independent

TABLE 3.—A COMPARISON OF THE MORTALITY IN THOSE CASES IN WHICH THE PLACENTA WAS REMOVED WITH THAT IN CASES IN WHICH IT WAS LEFT

Period	Placenta Removed—			Placenta Left—		
	Cases, No.	Deaths, No.	Mortality, per Cent.	Cases, No.	Deaths, No.	Mortality, per Cent.
A. 1809 to 1890	15	4	26.6	23	28	84.0
B. 1896 to 1900	64	17	28.3	38	17	47.7
C. 1900 to 1910	66	11	16.6	23	8	34.7
D. 1910 to 1919	18	2	11.1	4	2	50.0
E. 1809 to 1919	159	34	21.3	98	55	56.7

of the method of handling the placenta. These results compare very favorably with the 38.7 per cent. mortality which followed the use of drainage.

The mortality following the removal of the placenta, as well as that which accompanies its retention with and without drainage, is shown in Table 4. While these figures are somewhat deceptive, in that the placenta was left in the most difficult cases, they are sufficiently trustworthy to justify the statement that it should be removed whenever possible, and that when its retention is necessary, drainage should be avoided except in the presence of hemorrhage or infection.

Many of the fatalities recorded in this series were due to the fact that the operators had no definite plan of treating the placenta other than the idea that it should be removed. Usually the child was quickly extracted, and the removal of the placenta immediately attempted. Not infrequently an alarming hemorrhage necessitated the abandonment of all desire to remove this troublesome structure, and tampons were employed to stop the bleeding, the surgeon considering himself fortunate if the patient was alive at the end of the operation. As no one method is satisfactory for all cases, the surgeon should be familiar with the indications for, and contraindications to, each of the foregoing procedures. If a careful exploration is made before attempting any one of them, the most suitable plan for each case will be adopted before it has been made hopeless by the use of a faulty routine.

TABLE 4.—OPERATIVE MORTALITY OF THE DIFFERENT PROCEDURES IN CASES OF EXTRA-UTERINE PREGNANCY FROM 1890 TO 1919

Procedure Employed	Cases, No.	Deaths, No.	Mortality, per Cent.
Placenta removed	137	27	16.7
Placenta left to be absorbed	12	4	33.3
Placenta left (wound drained) until it came away	52	22	38.7

OUTLINE OF AN OPERATIVE ROUTINE

The following outline of an operative routine has been suggested by the study of these cases:

1. There should be a preliminary preparation for the control of hemorrhage and the treatment of the acute anemia which may follow. This should include sequestration of the extremities, to permit of autotransfusion. A donor whose blood has been previously tested should be at hand. An

assistant should be instructed in the technic of controlling hemorrhage by compression of the abdominal aorta.

2. On opening the abdomen, care should be used to avoid incising the placenta, as hemorrhage from this source may prove troublesome during the operation and, in those cases in which the placenta must be left, may necessitate the use of a tampon.

3. If possible, a careful exploration of the abdomen should be made before the sac is incised.

4. The extraction of the child should be as gentle as possible to avoid disturbance of the placental insertion.

5. As the handling of the placenta is the most formidable part of the operation, a second careful exploration should be made, if necessary, before deciding on the procedure to be employed.

6. Since the usual mechanism of controlling hemorrhage from the placental site is not followed when the pregnancy is extra-uterine, the vessels supplying this region should be ligated before the placenta is disturbed. Whenever this blood supply is accessible, the placenta should be removed.

7. The conditions which favor the removal of the placenta are:

(a) Its attachment by a pedicle which can be ligated.

(b) Easy exposure of the ovarian and uterine extremities of its blood supply.

(c) Easy exposure of the ovarian extremity of its blood supply on the side involved, and sufficient accessibility of the uterus to permit of hysterectomy from the opposite side, thus effecting a ligation of the uterine end of the placental supply.

8. After the removal of the placenta, the abdomen should be closed without drainage.

9. If the insertion of the placenta is such that preliminary control of its blood supply is impossible, its removal is contraindicated and great care should be exercised to avoid disturbing its attachment.

10. Under such circumstances, two plans of treatment are available:

(a) Closure of the abdomen without drainage, leaving the placenta to be absorbed.

(b) Drainage by the use of a Mikulicz tampon, after having sutured the sac to the margin of the wound.

11. The first of these procedures deserves employment whenever the preceding manipulations have not caused hemorrhage, and when infection is not present.

12. If the placenta is cut as the abdomen is entered, the hemorrhage may be arrested by the use of clamps and mass ligation of the cut surface, thus permitting its retention without drainage.

13. The retained placenta ultimately will be absorbed. While waiting for absorption there is a slight risk of secondary hemorrhage and infection from the adjacent intestines.

14. These complications will necessitate a second operation. Should suppuration take place, drainage may be obtained through the vagina.

15. The second method, marsupialization, is applicable to those cases in which the removal of the placenta is contraindicated and the presence of infection or hemorrhage from the placental site necessitates the use of a tampon.

16. The continuous use of drainage predisposes to peritonitis, from which a rather large percentage of patients died in former times, when this procedure was the one of choice.

CONCLUSIONS

1. Because of the high mortality connected with advanced extra-uterine pregnancy and the infrequent occurrence of this condition, every case should be reported.

2. The relatively large number of children that survived operation does not justify a disregard of the interests of the child.

3. The actual operative risk is less during the last month than at any other time.

4. There is very little added risk in delaying the operation until the thirty-eighth week if the patient is kept under observation.

5. Interference at the thirty-eighth week offers the best opportunity for the survival of the child.

6. Preliminary preparation for the treatment of hemorrhage should precede operation.

7. Before attacking the placenta, a careful exploration should be made to determine the proper procedure to be employed.

8. Removal of the placenta gives the best results.

9. The conditions which favor removal of the placenta are:

(a) Its attachment by a pedicle which can be ligated.

(b) Easy exposure of the ovarian and uterine extremities of its blood supply.

(c) Easy exposure of the ovarian extremity of its blood supply on the side involved, and sufficient accessibility of the uterus to permit of hysterectomy from the opposite side, thus effecting a ligation of the uterine end of the placental supply.

10. Preliminary ligation of the vessels supplying the placental site should precede all attempts at removal.

11. When preliminary control of these vessels is impossible, the placenta should be left in the abdomen.

12. Closure of the abdomen without drainage is indicated when hemorrhage and infection are absent, even though the placenta is not removed.

13. The retained placenta will ultimately be absorbed.

14. A slight danger of secondary hemorrhage exists, and infection from the adjacent intestines may occasionally occur before absorption is complete.

15. These complications will necessitate a second operation. If suppuration takes place, drainage may be obtained through the vagina.

16. Marsupialization should be limited to those cases in which the removal of the placenta is contraindicated and the presence of infection requires drainage, or in which hemorrhage necessitates the use of a tampon.

17. The continuous use of drainage invites infection in these cases, as is shown by the results obtained when this procedure was the one of choice.

200 Hicks Street.

Eggs in Liquid Form. During recent years the export from China of eggs in liquid form, preserved with boric acid, has developed very large proportions. Prior to the war relatively small quantities of this material were imported into England, the bulk of it going to Germany. The small quantities imported were used principally for industrial purposes, such as leather dressing, and to a limited extent for confectionery. After the outbreak of the war large consignments arrived at certain British ports as cargoes in prize ships, and since then large quantities have been imported in the ordinary course of trade. These products occasionally arrive in the form of whole egg mixed, but usually the egg yolk and egg albumin are sent separately. Samples of yolk taken from consignments arriving in the city of London were examined by the city analyst and found to contain boric acid in amounts varying from 1.35 to 2.08 per cent. When boric acid is relied on alone for preservative purposes the amount aimed at appears to be 2 per cent. Sometimes, however, common salt up to 10 per cent. is used with a smaller amount of boric acid. It is contended that these large amounts are necessary for effective preservation owing to the length of the voyage and the passage through the tropics. *Health Officer* 21:203 (June 14), 1919.

MISTAKES IN DIAGNOSIS REVEALED THROUGH THOROUGH EXAM- INATION *

J. RAWSON PENNINGTON, M.D.,
CHICAGO

Today the patient is demanding a more thorough examination than formerly. He is no longer satisfied with having his tongue inspected and being given a recipe for a box of pills. He demands an examination of his urine, blood, blood pressure, diet, etc. When he feels sick and comes to us for help, he expects us to examine his complaint and take an inventory of his general condition. A record of the findings must be kept. The business man keeps his; we should keep ours.

Early last year Mocquot,¹ the Paris surgeon, gave the details of a case showing the importance of such examinations: A soldier sustained a shell wound of the knee, which was treated by excision of the tract and cleansing, and—as the fluid from the joint was negative bacteriologically—by complete closure. Signs of infection developed on the fifth day, despite punctures and injections of ether; suppuration increased, and, in a few days, resembled furunculosis. The joint-fluid now gave a growth of *S. aureus*, and the man said he had often had crops of furuncles. Though other symptoms were absent, diabetes was thought of; but the urine contained no sugar. Hyperglycemia was next in mind, and nearly 3 gm. per liter was found in the blood. Sodium bicarbonate was now given with auto-vaccines, and after the fourth day improvement began. In six weeks the man was evacuated, completely cured of his hyperglycemia, and with the functions of the knee practically normal.

the examination revealed a profuse discharge of pus, fistulous openings, perianal infection and decided tenderness over the sacrum. I advised operation, but it was declined.

In April, the patient was again operated on by another and eminent surgeon. A year later Dr. M. Nuta brought him to my office, having discovered a large pocket of pus over the sacrum. This I drained, finding, as surmised at the former examination, necrosis of the sacrum and a sinus into the rectum posteriorly. There were five other fistulas into the rectum, and one into the anal canal (Fig. 1).

Later on, I chiseled away the diseased bone and incised the fistulous tract extending over the sacrum and the coccyx to within about 1 inch of the rectum. The remaining portion of this and the other fistulous tracts were then enlarged and a seton passed through each. All the tracts except one, which is lined with epithelium and not discharging or giving any trouble, are closed. As the sphincters were not divided, the contour and function of the anus are preserved, and the patient has recovered much of the control lost as a result of the former operations (Fig. 2).

Fig. 3 (Case 2).—Division of rectovaginal septum. Patient has no control whatever over pus and bowel contents.

This report is submitted because the surgeons who had previously operated on the man—"stumbled," as Saint James² says—as to the primary cause of the trouble: diseased sacrum.

CASE 2.—Mrs. F. M., aged 35, had had syphilitic stricture of the rectum for three years, and was operated on for a rectovaginal fistula in June, 1917. The wound did not heal and was followed by incontinence of feces and pus (Fig. 3).

I saw her first in October, 1917, and made a left inguinal colostomy the next month. A year later the rectum was removed by the abdominoperineal route. A short segment of the friable and syphilitic colon, distal to the colostomy, was closed at the distal end, but not removed on account of the patient's condition. Excrement passed into this segment from the colostomy opening. The reinforced purse string gave way, and the feces and pus escaped into the abdomen out through the perineal incision, and a fistulous tract in the posterior vaginal wall (Fig. 4). The patient had periodic attacks of pain in the region of the stomach, which, because of the history, were diagnosed by myself and others as "gastric crises." Later, I discovered that the "crises" were caused by the accumulation of feces in the perineal incision and the vaginal fistula, and that the pain ceased immediately on the removal of the segment of colon that had opened.

I report this case because of the "stomach pain," its cause, and my error as to the etiology.

CASE 3.—Mrs. H., aged 51, was referred to my clinic at the Illinois Post-Graduate School by Dr. Wunderlick, in September, 1916, because of constipation. She had been treated for ulcer of the stomach for the past year and was

FIG. 1 (Case 1).—Division of rectovaginal septum and removal of pus.

FIG. 2 (Case 1).—Appearance of the wound shown in Figure 1 eight months after the operation.

REPORT OF CASES

CASE 1.—Mr. W., aged 40, came to my clinic at the Illinois Post-Graduate School in March, 1916. He had pain and constant discharge of pus from an ischio-rectal abscess which had been opened in July, 1912, had never healed. As

* Read before the Section on Gastro-Enterology and Proctology at the Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

¹ J. M. Mocquot, P. Presse, vol. 26 (Feb. 13, 1917).

² "For whom ever shall keep the whole law and yet stumble in one point, he is become guilty of all." James (Revised Version) 2: 10.

to be operated on for it in the near future. She was obstinately constipated, complained of loss of appetite, loss of weight, and pain in her stomach. The rectum contained a number of small, tender, cicatricial knots, probably the result of a former hemorrhoidal operation. Following the removal of these knots, her bowels became regular, the stomach pain ceased, her appetite improved, and she gained in weight.

Cases 2 and 3 show that anal and perianal irritation may cause pain in the region of the stomach, and that in such cases the rectum should be examined.

CASE 4.—H. W., a man, aged 38, was referred to me by a prominent Chicago surgeon in March, 1918, because of a supposed hemorrhoidal condition. I found he was constipated, had dragging pains in each groin, backache and a very long scrotum, while the rectal trouble was of little consequence.

So he was referred back with the suggestion that the surgeon amputate the scrotum, which was done. No improve-

ment followed. He was again anesthetized to ascertain the cause of the hemorrhage. It seemed due to slight oozing from the mucosa, though no distinct lesions could be seen. The reaction to a Wassermann test was + + + +. Antisyphilitic treatment finally controlled the bleeding, with consequent improvement in the general health.

CASE 6.—J. R., a man, aged 57, complained of hemorrhage and loss of weight. Examination revealed large protruding internal hemorrhoids, which bled on slight provocation. These and a small growth opposite the prostate were removed. He made a very tardy recovery; the bleeding continued.

He was again anesthetized to ascertain the cause of the hemorrhage. It seemed due to slight oozing from the mucosa, though no distinct lesions could be seen. The reaction to a Wassermann test was + + + +. Antisyphilitic treatment finally controlled the bleeding, with consequent improvement in the general health.

Cases 4, 5 and 6 show the importance of a routine Wassermann test.

CASE 7.—R. P., a boy, aged 2½ years, was greatly emaciated and had a facial expression like that of an old man. In addition to prolapse, he had an eczematous eruption around the anus, penis, scrotum and pubes; and a secondary infection, of the same type, of the nose and mouth, and around the finger nails (Fig. 5). The itching about the anus was intense at times. Cultures from each region produced the same type of bacteria.

CASE 8.—Mr. G. was referred by his family physician to be treated for hemorrhoids, fissure and pruritus. Operations were performed for the first two, but recovery was greatly retarded. On more careful examination, it was found that the patient had a nasal infection, apparently of the same type as that of the anal region (Figs. 6 and 7).

Cases 7 and 8 show that anal infections may be transmitted to the nose or mouth by the hand. Similar

Fig. 4 (Case 2).—Fistulous tract from the sigmoid passing inter-intestinally and out through the perineal incision, and a fistulous tract through the posterior vaginal wall.

ment followed. Then I operated on him for the rectal trouble, and this operation, also, gave little or no relief. Later, when a Wassermann test was suggested, he became very indignant, but finally consented. The test gave a positive reaction, and specific treatment relieved him of his troubles.

CASE 5.—J. P., a girl, aged 8 years, had been severely constipated since birth, and passed a great deal of mucus with her stools. She also had periodic attacks of abdominal pain, with nausea and vomiting. The pain seemed to be located just to the left of the umbilicus. These attacks, which began early in 1915, usually occurred every month or six weeks, lasting from three to four days; at one time the interval was three months.

Late in 1915 she was very ill, and her condition was diagnosed as "pneumonia" and "hemorrhage of the brain." She became paralyzed on one side during this illness, but the paralysis began to subside after two months. When I saw her, she had been given treatment for the constipation and

Fig. 5 (Case 7).—Patulous anus and ulceration of the perineal and anal region.

Fig. 6 (Case 8).—Delayed healing six weeks after operation.

Fig. 7 (Case 8).—Nasal ulceration of the nose.

conditions have been noted in pruritus ani, of which I shall have more to say in a future article.

CASE 9. Miss B., aged 44, had a perirectal abscess, which was opened, April 4, 1916, but failed to heal. Five weeks later she had an operation for a fistula; this likewise refused to heal. There was incontinence of feces following the last operation.

I first saw her in September, 1917, when the roentgen ray (Fig. 8) and sigmoidoscopy disclosed a fistula with the

internal opening at the rectosigmoidal junction, just above a large hypertrophied rectal valve. This internal opening was approximately 6 inches from the anus. The proctoscope (Fig. 9) was of sufficient length only to reach the distal surface of the valve. It was with difficulty that the sigmoidoscope,

Fig. 8 (Case 9).—Fistulous tract.

seven-eighths inch in diameter (Fig. 9), was passed through the valve strait, which verified the diagnosis.

December 7, I passed a wire ligature through the fistulous tract, twisted it taut on the intervening tissues, and made a second roentgenogram three days later (Figs. 10 and 12). The final method of dividing the tract is shown in Figure 11. The recovery was uneventful.

This case illustrates the importance of a thorough examination and careful diagnosis before operating for fistula.

CASE 10. J. A., a man, aged 59, consulted me in November, 1918, complaining of loss of weight, "tired feeling," loss

of the rectum and the sigmoid, was utilized in vain to ascertain the cause.

An exploratory laparotomy was performed by Dr. Culbkins, and the gallbladder was drained. No evidence of malignancy was detected. The patient died, Feb. 11, 1919. A necropsy failed to detect any definite cause of the jaundice. I removed the sigmoid and the rectum; there was a decided narrowing at the rectosigmoidal junction; the sigmoid itself was immensely dilated and the wall very thin.

Did this strictured condition and the resultant constipation cause the jaundice? At any rate, the condition might have been diagnosed during life had my colleagues and myself made a complete examination.

NEED OF MORE THOROUGH EXAMINATIONS

The foregoing and many other examples that could be cited show that while one may limit his practice to a certain specialty or region of the body, his treatment should be based on a thorough and complete examination of the whole body, the patient's habits, etc.

To examine a patient complaining of heart trouble by auscultation, percussion, etc., and not investigate

Fig. 10 (Case 9).—Schematic: a probe with an eye in the distal end carries a thread through the fistulous tract. The thread, to which is attached a wire, is grasped by the forceps and pulled out through the rectum. By tension and twisting, the wire was made taut around the intervening tissues. On the sixth day it broke and was replaced with linen ligature, as shown in Figure 11.

the nose, mouth, throat, rectum and other organs, is to be guilty of neglect. The same is true if the patient complains of stomach trouble, or of appendicitis, and in the case of many other ailments.

Recently, Dr. George H. Weaver³ reported a case of streptococcus meningitis in a woman, aged 25, with recovery. He says: "The tonsils had been removed a year before" the onset, and that "repeated and thorough examinations of the ears, nose and throat by Dr. Robert Sonnenschein failed to detect any condition that might have been the focus of infection primary to the meningitis." There is no record, however, of a rectal examination in this case. Might not the primary cause have been located in the intestinal tract or rectum?

Captain Armitage⁴ reports a case of brain abscess and death following amebic abscess of the liver. The

Fig. 9 (Case 9).—A distal end of the proctoscope and sigmoidoscope. The proctoscope was of sufficient length only to reach the distal surface of the valve.

of appetite and constipation. He was distinctly jaundiced, and there was a boardlike hardness, especially over the gallbladder and pancreas, with tenderness in the left iliac region.

I referred him to the clinical services of the Northwestern University Medical School, where he was examined and treated. Every known scientific procedure, except examina-

³ Weaver, G. H.: A Case of Acute Streptococcus Meningitis With Recovery, *J. A. M. A.*, **72**:137 (May 10) 1919.
⁴ Armitage, F. L.: Amebic Abscess of Brain Following Amebic Abscess of Liver, *J. Trop. Med.*, **23**:69 (April 15) 1919.

says: "Motile endamebas were found without difficulty; they . . . resembled exactly the endameba seen in . . . dysenteric stools." Furthermore, bacteriologic examinations of pus from the brain abscess showed streptococci, staphylococci and *B. coli-communis*.

This case shows that infection may be carried from the intestinal tract and rectum to the brain. And it discloses, moreover, that in many diseases of the brain and meninges, these organs should be examined for the primary focus.

A few months ago Desmarest,⁵ another surgeon of Paris, stated that he had encountered fifty cancers of the rectum in his wards within three years, a large proportion too far advanced for operation. This was because the previous medical attendants had treated the bleeding and discharge as enteritis, colitis or "piles," and had made neither digital nor instrumental examination.

A gynecologist would not dream of treating disease of the pelvic organs without a vaginal examination through the speculum. It is my firm belief that the use of the proctoscope is equally imperative, and that the gastro-intestinal tract and rectum should be more frequently and systematically examined in constitutional and rectal diseases.

31 North State Street.

ABSTRACT OF DISCUSSION

DR. FRANK C. NEOMANS, New York: Sometimes you cannot get the injection through the fistulous tract because the bismuth paste is too thick. If you use an aqueous solution of methylene blue it is more apt to go through and you can then make a diagnosis very simply by recognizing the blue in the rectum. As to the proctoscope: My experience is that the proximally lighted instrument is preferable to those

Fig. 11 (Case 9).—Diagrammatic: two ligatures—one for an emergency, the other for immediate use—passed through the fistula and out through the rectum, enclosing intervening tissues. To make tension on the ligature, the free ends are passed through the hole in an inflated vaginal pessary, which rests on the anal region, and wrapped around a flat stick that rests on the elastic pessary.

lighted distally for the reasons that (1) feces often covers the distal light and obscures the field, (2) the narrow auxiliary tube for the light carrier is cleaned and dried with

difficulty, hence the little bulbs are often shortcircuited and burn out and (3) they cannot be sterilized without injury by frequent boiling as is necessary when examining cases of tuberculosis, syphilis and dysentery. I devised a tube to overcome these defects.

DR. JOHN L. JELKS, Memphis: As to Dr. Pennington's operation in that case where he suggests a major silver wire operation, I must differ with his technique. What would be the objection if you would split that area even to the peritoneum and sewed that intestine up and drained that area—not closed it but drained it—as you would any ordinary perirectal infection? You would not put silver wire in the ileum; then why put it here?

DR. E. G. MARTIN, Detroit: I would like to suggest one method of examination which does not seem to be in general use (at least it has not been mentioned today), and that is the observation of the barium enema under the fluoroscope during its administration. It is realized that in a multiple fistula one would not expect to observe the bismuth entering the tracts because it would not be forced in there, but in a pathologic anastomosis, of the sigmoid and cecum for instance, it is of great value. In the last case in which I used this method, there had been difficulty in diagnosis; the enema was clearly observed to fill the rectum, and to pass through a little tract filling a part of the cecum; immediately following, the bismuth passed up around the colon and completed the filling of the cecum. That point would not have been demonstrated clearly without the fluoroscopic observation of this enema during its administration. The technique is simple, and the later study of the stereoscopic plates will be made more comprehensive.

Fig. 12 (Case 9).—Wire ligature through fistula and rectum.

The Symbiotes.—This is the title of a book recently issued by Prof. P. Portier, maître de conférences at the Faculté des Sciences at Paris, professor at the Institut Océanographique. He has coined this term to express certain micro-organisms which live within our cells and supply nourishment to the cell. He says that all the biologic synthesis of the cell is the work of this living symbiote. It is the substratum of all synthesis. If they are lacking, the cell dies as it is unable alone to proceed in the work of repair. These intracellular symbiotes come from without and they have to be constantly renewed. They are killed by a temperature of 120 C. The symbiote in the cell is called by the histologists the mitochondrion, and the globulin in the circulating blood is merely the *symbiotes en voyage*. It is the lack of symbiotes which is responsible for the deficiency diseases, as the symbiotes accumulate in the periphery of grains, for example, and are discarded in the polishings of rice. This is the explanation of the vitamin theory: It is the lack of living symbiotes from which the subject is suffering. By injection of cultures of the symbiote he has saved animals succumbing to deficiency diseases; the paralysis or other disturbance promptly disappeared and the animal was soon as lively as before. A full analysis of Portier's book is given, with some of the illustrations, in the *Presse Médicale*, Feb. 24, 1919, and his views in regard to the participation of the symbiotes in fertilization of the ovum, in cancer, etc. The review concludes, "Portier has opened a new field of bacteriology. True or false, his theory will be the starting point for a host of works on symbiotic bacteriology."

THE ETIOLOGY OF COMMON WARTS

PRELIMINARY REPORT OF AN EXPERIMENTAL
STUDY*

UDO J. WILE, A.B., M.D.

Professor of Dermatology and Syphilology, University of Michigan
Medical School

AND

LYLE B. KINGERY, B.S., M.D.

Professor in Dermatology and Syphilology, University of Michigan
Medical School

ANN ARBOR, MICH.

That certain micro-organisms can, by direct implantation, give rise to disorders of keratinization, notably localized hyperkeratosis, is an accepted fact clinically and bacteriologically. Thus, the etiologic rôle of the gonococcus in the production of blenorrhagic keratoses, the tubercle bacillus in its relation to verruca necro-

genica, and the gonococcus and pus organisms as causative agents in the production of acuminate condylomas stand out as striking examples of the aforementioned fact.

HYPOTHESES EN-
TERTAINED

In explanation of the etiologic factor in the production of common warts there have been advanced at various times the opinions that they are caused by an infecting organism, trauma or a foreign body. There are many clinical examples which stand out in favor of each of these hypotheses.

The frequency with which verrucae occur at points of

trauma, notably on the hands and feet, would at first glance speak strongly for trauma as the causative agent. In favor of a foreign body as a possible cause are the numerous clinical examples of localized hyperkeratosis following accidental implantation of thorns, thistles, bits of glass and steel. That localized hyperkeratosis of a warty type undoubtedly occurs following such foreign body implantation is, however, in no way conclusive proof of the etiologic moment of the foreign body itself. The injury incident to the entrance of the foreign body can as readily be accepted as the portal of entrance for an infecting organism.

The clinical evidence in favor of an infectious agent in the causation of warts is extremely suggestive. The appearance of so-called daughter warts following the

initial appearance of a large wart, the appearance of warts on contiguous and apposing surfaces, so frequently observed, the occasional occurrence in small groups of individual warts in close association, all lend color to this view.

Fig. 2.—Early wart appearing at site of inoculation two weeks after injection of the virus.

From the experimental side, of interest in this connection is the observation of Payne,¹ who, after removing the surface of warts on a patient with his thumb nail, subsequently developed typical warts underneath the nail on his own finger. Similar observations are recorded by Lanz² and Stelwagon. Fox, Allen and Stelwagon have recorded the coincident occurrence of warts and molluscum contagiosum; and Fox and Allen,

Fig. 3.—Small, flat warts at sites of inoculation; larger wound is site of biopsy.

at least, are inclined to regard the coincidence as suggestive of an infectious agent.

In 1889, Kuhneman³ described a bacillus which he found in the epidermis of verrucae. He reports having

* Read before the Section on Dermatology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June 1, 1919.

cultivated the organism, and with cultures to have reproduced wartlike growths in laboratory animals. His results have never been substantiated by other observers. In 1893, Variot⁴ inoculated the blood from small verrucae into one of his assistants "with positive results."

Fig. 4.—Typical verruca vulgaris developing suddenly from a small, flat wart eight weeks after inoculation.

By far the most elaborate experimental study, however, is that of Jadassohn,⁵ in 1894. This author implanted small bits of tissue from warts under the epidermis. His experiments, undertaken over a long period of time, included seventy-four inoculations of this type. Of these, thirty-one gave positive results and led to the development at the site of implantation of typical warts. The incubation period of these varied from seven weeks to three months. It

is of interest to note that in these experiments none of the warts attained a large size, and all, after persisting for a time, disappeared spontaneously. Histologic studies on excised experimental lesions showed them to be typical verrucae.

Within the last few years, similar studies have been made by Ormsby⁶ and others in connection with verrucae plantaris.

During the past year, we have begun an experimental study embodying the attempt to produce localized hyperkeratoses by the injection of a filtrate of

Fig. 5.—Biopsy of one of small warts shown in Figure 3: normal skin at one end of section and beginning hyperkeratosis at other.

wart material. We began this work with the distinct conviction that warts might possibly be caused by a filtrable virus.

REPORT OF EXPERIMENTS

Our experiments were performed in this manner: The wart material was taken by curettement and divided into two portions. One portion was placed in glycerin for a later experiment. The remaining half

was immediately ground up in a mortar with an exceedingly small amount of physiologic sodium chloride solution. This mash was then passed through a small Berkefeld filter, the filtering surface of which had been reduced by sealing all but the upper surface with paraffin (Fig. 1). The resultant filtrate, gathered under negative pressure, was immediately placed on slant agar to test its sterility, which was uniformly negative. It was then injected by means of a fine needle on a tuberculin syringe intracutaneously into the skin of the hands of ourselves and assistants.

Fig. 6.—Later stage in development of wart, showing proliferation of the papillary tufts and marked hyperkeratosis.

Our first experiment in this way was performed, Feb. 4, 1919. March 5, or approximately four weeks later, small, flat, shining, wartlike lesions were found to have appeared at the sites of inoculation in one of us. Small lesions occurred, March 12, in a second one of us, and, March 26 (Fig. 3), in the third subject of the experiment. The lesions were unaccompanied by any subjective symptoms, and observation showed them to increase slowly in size, taking on more and more the characteristics of flat warts. A certain tendency to spontaneous resolution was noted in some. For the most part, however, warts produced by the inoculations in February are still present on our hands. In only one case did the wart reach a very large size. In this case, at about the eighth week, a small, flat wart on the inner side of the right middle finger suddenly grew until, in a few days, it reached the size of a large pea,

Fig. 7.—Early flat wart: marked hyperkeratosis; obliteration of papillae.

with a distinctly warty and papillary surface (Fig. 4). Microscopic examinations of the lesions were made at repeated intervals from the time of their appearance. The first lesions examined (Fig. 5) showed the typical localized acanthosis described by Uma, Auspitz and others as the initial change in warts. In every case in which biopsies were made, small pieces of normal skin were removed from the adjacent areas for comparison. Hypertrophy, elongation and dipping down of the interpapillary tufts were noted in the later lesions.

5. Jadassohn: *Arch. f. Dermat.* 1896, 5th Congress.

6. Ormsby: Personal communication to the authors.

In the large wart, which was excised about nine weeks after implantation, the typical structure of an old wart was noted (Fig. 10). In this picture, there is not only marked hyperkeratosis with proliferation and elongation of the interpapillary tufts, but also a mild

Fig. 8—Later stage in development of warts, showing transition from flat to papillary wart, hyperkeratosis, acanthosis, thickening and dipping down of interpapillary tufts.

inflammatory reaction to be noted deeper in the corium. As a control experiment, injections were made into one of our staff with a mash made up of small bits of normal epithelium in exactly the same way as was done with the wart material. The control experiments of this nature remained entirely negative.

Our second experiment, undertaken after the successful outcome of the first, was made to determine the possible retention of virulence of the virus if kept in glycerin. For the purpose of this determination, we

Fig. 9—Later stage in development of flat wart into papillary wart, showing marked hyperkeratosis, increase in stratum granulosum, prolongation of interpapillary tufts, inflammatory reaction in the cutis, and slight vacuolization in the cells of the rete.

been preserved in glycerin. March 12, therefore, a few days after the appearance of our first experimental lesions, we injected two members of our staff in exactly the same places and under exactly similar conditions with the sterile filtrate of the glycerin-preserved material. Thus far the results have been negative.

As may be seen from the accompanying photomicrographs, the histologic picture as well as pictures of the clinical appearance is typical of that of early warts.

The histopathology of verrucae vulgaris is in no way a matter of dispute, and it is not our purpose here to enter on a discussion of it.

Sufficient time has not elapsed for us to determine the influence of physical changes, such as light, heat and cold, on the virulence of the filtrate which we obtained. It is contemplated that experiments on this basis will be carried out.

The negative outcome of the glycerin-preserved filtrate is by no means conclusive proof, because of the insufficient lapse of time, the insufficient number of experiments, and other factors not determinable. Further experiments along this line will be carried out.

CONCLUSIONS

1. The sterile filtrate of wart material injected intracutaneously is capable of producing localized hyperkeratoses which are clinically and pathologically identical with verrucae vulgaris.

Fig. 10—Section taken from well developed wart on finger shown in Figure 4, revealing marked hyperkeratosis, increase in stratum granulosum, prolongation of interpapillary tufts, inflammatory reaction in the cutis, and slight vacuolization in the cells of the rete.

2. The initial experimental lesion starts as a flat wart which in no way differs from that seen in verruca plana.

3. Interpapillary hypertrophy, inflammation and marked hyperkeratosis, we believe, occur as secondary traumatic manifestations, and we are agreed with Unna that the initial change consists of an acanthosis and flattening of the papillae.

4. Without denying that it is still possible that localized hyperkeratosis resembling verrucae may be due to traumas or foreign bodies, it is definitely demonstrated that such changes can be caused by a filtrable virus. It is not unlikely that when trauma and foreign bodies apparently are present as inciting factors, they may merely represent the point of entrance of an infectious agent such as has been determined in these experiments.⁷

ABSTRACT OF DISCUSSION

DR. WILLIAM T. CORLETT, Cleveland: The subject of warts is a very disagreeable one, because it is so elusive; in fact, everything pertaining to warts seems elusive, except the wart itself which often is most tenacious. We do not know much about the etiology of warts, and their treatment is disappointing. In several instances they have appeared to me to be contagious. In fact, I have seen a number of cases that seem

an ultramicroscopic organism. We feel that further investigation will prove it to be such.

DR. LYLE KINGERY, Ann Arbor, Mich.: As Dr. Wile has said, we were familiar with Dr. Smith's work. As for producing tumors in plants, he was able to do it with ammonia and copper salts. Whether there was anything mixed with our material, such as small drops of blood, remains to be shown. We hope to do more work on the subject.

Fig. 11.—Normal skin taken from neighborhood of wart for comparison.

to justify this conclusion. Nothing very definite thus far has been brought out concerning their etiology. I, therefore, wish to congratulate one of the youngest members of the section in attempting to work out, in the laboratory and under the direction of Dr. Wile, this excellent demonstration of the subject which should be regarded as promising and deserving of further and more conclusive study.

DR. WILLIAM C. MACCARTY, Rochester, Minn.: I have been very much interested in the doctor's experiments because I am interested in the histogenesis of such organisms. Perhaps you are familiar with the histogenesis of neoplasms and with Smith's work. I have followed his work well, in fact. I was with him up to a month ago. He isolated his organism by producing plant tumors. He carried on these experiments in regard to the parasitic idea of the neoplasms and it was with great difficulty that he worked this out. A year or so ago he produced some similar neoplasms by chemical means, and in plants he produced neoplasms by injuring the water supply and the roots of the plants. I hope that Dr. Kingery will not draw too positive conclusions. We are all interested in this work. Experiments should be made from a physical standpoint, as he has suggested. I wish to express my appreciation as a pathologist of this experimental work and hope that he will not only continue it but that others will carry out the experiments.

DR. HARRY G. IRVINE, Minneapolis: I wish to add my appreciation of this contribution of Drs. Wile and Kingery and also of Dr. Kingery's excellent presentation of the subject. It is a very valuable and excellent attempt at arriving at the etiology of this very common disease. In some instances the lesions began as ordinary warts and later became verruca vulgaris. This is interesting because while we have thought that they were more or less alike, we know that one is affected by certain treatment and the other not at all. I think this is especially interesting.

DR. UDO J. WILE, Ann Arbor, Mich.: In answer to Dr. MacCarty I may say that we knew of Dr. Smith's work and with due allowance for his results, I do not think we have overstated our case. The facts are these: Material from warts passed through a Berkefeld filter produced lesions which were clinically and pathologically identical with warts. Warty growths undoubtedly can be produced by other organisms; thus the tubercle bacillus and the gonococcus undoubtedly produce warty growths. We believe that common warts, however, are produced by this filtrable virus. If a filtrable virus can produce marked epithelial hypertrophy, may not this have a bearing on the growth of epithelium in other tumors, for example, malignant tumors? It is at least suggestive. As to the nature of the virus, we say it can not be cultivated by ordinary methods, but nevertheless it may be

A NEW ADHESIVE MATERIAL
FOR TRACTION

W. E. CUNNINGHAM, M.D.
NEW YORK

The fixed traction and traction suspension methods of treating fractures have been so widely adopted, and with such satisfactory results, that anything which might increase their application is worthy of a few descriptive lines.

Of the available substances for adhesive traction, Sinclair's glue is undoubtedly the most satisfactory. At times, however, because of the variability of the fish glue from which it is made, it lacks the necessary adhesive force. It is irritating to certain skins; but this may be due, partly, to faulty preparation or to applying it too hot. Salicylic acid has been used as a preservative according to some of the formulas. This should be avoided, as it increases desquamation; thymol is equally effective as a preservative. Frequently, it is necessary to wait some time after it is applied before traction can be made, and a relatively large area of skin must be available for its application.

Fig. 1 (Experiment 1). Traction, suspension apparatus for fracture of femur with 30 pounds of traction applied.

Many of the foregoing disadvantages may be avoided by the use of a solution of celluloid in acetone. For several months past, experiments have been made with a 5 to 10 per cent. solution of celluloid in acetone, and we have found that this makes an excellent adhesive material. Twenty-five applications of this solution

have been carefully observed, and it is believed that the scope of traction is increased by its use.

Through the kindness of the American Celluloid Company we secured a supply of celluloid scrap from which an excellent solution may be made. The first

Fig. 2 (Experiment 7).—Suspension of leg for fracture of metatarsus; 10 per cent. solution to dorsal and plantar surfaces of great toe only.

experimental work was done with celluloid combs, as it was impossible to obtain celluloid scrap in France.

Given a standard adhesive material, experiments should be conducted to determine the relation between the area of surface glued and the amount of traction that can be applied. The skin tolerance for maximum weight should be known. This will vary in different parts of the body, and probably indirectly with mobility of the subcutaneous tissues.

PREPARATION

The required amount of celluloid scrap and acetone are placed in a dry, clean, wide-mouthed bottle, and securely stoppered. The bottle is then shaken or agitated at intervals, and the solution is ready for use in from twenty-four to forty-eight hours. When properly made, it should be an almost clear, homogeneous, syrupy fluid. The experimental solution of combs was often lumpy and contained some acetone insoluble material.

Acetone is very volatile, so precautions should be taken to prevent evaporation. During the war when these experiments were carried out celluloid was difficult to obtain and acetone sold as high as 30 francs a liter; but the antewar selling price of acetone, which is used in the aeroplane industry, was 35 cents a pound. One liter will make sufficient material for from thirty to forty applications.

MODE OF APPLICATION

In the experiments, no careful preparation of the skin was made. It should, however, be absolutely dry; and the preliminary use of a few cubic centimeters of acetone on the region to be employed may aid in this respect, but is not necessary. A layer of celluloid solution is rapidly applied by means of a small, stiff brush. The quantity should be sufficient to soak through the

strip on which traction is to be applied, and a thin coating should be applied externally to get out all the wrinkles and air bubbles. Canton flannel is the best material for strips, but a double layer of gauze or muslin that is neither too hard nor too finely woven may be used.

Iodin and also picric acid and alcohol should be avoided as far as possible on areas to which any type of adhesive is to be applied. Both these drugs increase exfoliation, and we well know the reaction of certain skins to the former. We believe, with Sinclair, that the part should not be shaved before adhesive material is applied, for the hairs, if abundant, increase the efficiency of the adhesive, like hair in plaster. If there is delay in putting on the strip, the skin should be recoated, for it dries out in a thin, flexible film in a minute or two. The application of a circular gauze bandage over cotton increases the effectiveness of adhesion and should be used. It is needless to state that the solution is combustible; therefore it should not be heated, and containers should be so labeled.

Flexible metal tubes can be used as containers, direct application being made from them. This type of dispensing could be utilized for emergency use, as this method has proved practicable, but it would add materially to the cost. Muslin strips have been impregnated with the solution, with the hope that it might be used like adhesive plaster, acetone being added when applied; but this method has proved unsatisfactory.

REPORT OF EXPERIMENTS

EXPERIMENT 1 (Fig. 1).—An application of a 4.9 per cent. solution of celluloid combs was made to the leg (there was no fracture in this case). 3-inch muslin strips being used, applied over an area of 6 inches. Traction of 30 pounds was applied as soon as the leg could be put up in apparatus and timed just less than ten minutes. Because the patient was so uncomfortable, 10 pounds were removed at the expiration of six hours and 10 more after seven hours. Traction and

Fig. 3 (Experiment 9).—Traction, countertraction metacarpal splint. Adhesive applied to volar forearm and volar and dorsal aspects of fingers.

the strips, which were still holding securely, were removed after seventeen days. There was no irritation of the skin.

EXPERIMENT 2.—An application of a 10 per cent. solution of celluloid combs was made to the lower humeral region over an area of 2 by 3 inches, for a fracture of the lower end of the humerus. To this area, with the inclusion of the forearm, Sinclair's glue had previously been applied and the skin was blistered. Immediate traction by the hand was secured and held firmly by a pin in the notches of a Jones splint. An anesthetic was necessary for reduction, so the strip was removed at the end of forty-eight hours. The greater part of the skin had blistered to the vascular layer, and when

removed, left multiple bleeding points. The traction was undoubtedly excessive for the skin tolerance.

EXPERIMENT 3.—An application of a solution of celluloid combs was made to the anterior two thirds of the plantar surface of the foot for dorsiflexion in traction suspension (fracture of femur). Sinclair's glue had slipped four times, the last time within forty-eight hours. The strip applied with celluloid pulled away spontaneously after thirty-eight days. The inner side of the muslin was covered by a layer of epidermis, but the skin beneath was without irritation.

EXPERIMENT 4.—An application of a 5 per cent. solution of celluloid combs was made to the lower femoral region over an area of 3 by 5 inches for a fracture of the upper one third

Fig. 4.—Molded sole plate, traction bar in position.

of the femur. Fifteen pounds traction was immediately applied. One side pulled away after fourteen days, and from its appearance it was concluded that the application had been unsatisfactory. An area of desquamated skin about 1 inch square remained attached to the strip, which did not appear to be holding at other points. The skin was also desquamating from picric acid.

EXPERIMENT 5.—An application of a 10 per cent. solution of celluloid combs to the skin was made with a 5 per cent. solution to the overlying muslin strip, in the malleolar regions over an area of 3 by 6 inches, with a pressure bandage over the cotton for a fracture of the lower third of the tibia and fibula. There was a wound $2\frac{1}{2}$ inches above the tip of the malleolus. The foot in this instance was edematous, and there was a pressure sore over the heel. Immediate traction was secured by the hand and held by a heavy rubber tube. The patient was evacuated after twenty-seven days with the strip still holding.

EXPERIMENT 6.—An application of a 5 per cent. solution of celluloid combs was made to the forearm over an area of 3 by 5 inches for a fracture of the humerus. A traction of 3.5 pounds was applied. One half of the area had been blistered by a previous application of Sinclair's glue. After seventeen days the strip was removed and it was found that the blister had healed beneath. The patient was put in a plaster.

EXPERIMENT 7 (Fig. 2).—An application of a 10 per cent. solution of celluloid combs was made to the dorsal and plantar surfaces of the great toe, distal to the metatarsophalangeal joint, for fracture—dislocation of the tarsometatarsal joint. Suspension of the leg by traction on the great toe, using a muslin strip 1 inch wide and a firm bandage, was secured. The leg was taken down at the end of three days to prepare for an operation. The skin was in excellent condition. About one half of the time the patient was so uncomfortable that the heel was partially supported by a pillow.

EXPERIMENT 8.—With a 6 per cent. solution of celluloid scrap applied to the forearm over an area of 1½ by 6 inches, Canton flannel strips being used, sufficient pull was exerted, three minutes after application, to pull the patient with the hospital bed without casters several feet, and the strip was still holding.

EXPERIMENT 9 (Fig. 3).—In a compound fracture of the second, third and fourth metacarpals with extensive laceration, a composite molded plaster and aluminum splint were made fast to the forearm with a 6 per cent. solution. Traction was secured by strips fastened to the fingers and secured by rubber tubes to a frame. The patient was under observation for almost two months, and the splint was still intact.

The celluloid solution was applied with satisfactory results in numerous other cases of fracture of the femur and humerus. Since these cases presented no points of added interest, they need not be described.

SOLE PLATE TRACTION

The subject of sole plate traction has not such a field as it had before Nov. 11, 1918, but occasionally in civil life, in crushing injuries of the lower extremity or compound fractures with badly lacerated soft parts, the method of traction becomes a puzzle. There are cases when traction strips cannot be used, and cases when Steinmann pins, Besley tongs, or Finocchetto bands cannot be used without the risk of opening up new foci for micro-organisms to lodge and thereby increase infection.

It was for just such cases that Sinclair devised the "skate." This mechanism was glued to the sole and strips for reinforcement were carried over the dorsum of the foot. In certain cases the skin of the dorsum of the foot is in such condition that strips cannot be applied.

At No. 1 General Hospital, B. E. F., we had many cases of this type, and used an accurately molded sole plate with a 10 per cent. celluloid solution. The plate (Fig. 4) is made as follows: A light plaster impression of the plantar surface of the foot is made of four or five layers of bandage over Canton flannel long enough to extend from just beyond the big toe to the attachment of the Achilles tendon. This is accurately molded by hand and held in position for half an hour by a snug bandage over cotton. This is removed and reinforced by an aluminum strip, which is secured to the impression by a plaster bandage to which are attached traction cords. These should be so placed that the line of pull will pass through the center of the internal mal-

Fig. 5.—Fracture of femur, laceration of leg; molded sole plate completed and made of traction; breaking stress, 38 pounds.

leolus, which position will prevent foot drop. After the mold has been thoroughly dried in an oven, a quantity of the 10 per cent. celluloid is poured into it and the whole is applied to the foot. A bandage over cotton is necessary to hold it in place until thoroughly dried. From one to two hours are allowed for this, and a 12 to 15 pound traction may be used. The sole plate seen in Figure 5 pulled away after 38 pounds had been applied. Several of these with from 9 to 15 pounds of traction have been observed for periods of thirty days and more.

No attempt has been made in any of these cases to demonstrate the effectiveness of external traction, for this seems to be an accepted fact; but an attempt has been made merely to show that celluloid solution is an adhesive which can be used when other materials fail.

CONCLUSIONS

1. From 5 to 10 per cent. celluloid in acetone makes an excellent adhesive material.
2. Its rapidly volatilizing quality permits of immediate traction.
3. In high concentration it can be used when only small areas of skin are available.
4. It is insoluble in water; hence, it is not affected by perspiration or climatic changes.
5. Solutions which are likely to increase desquamation should not be used prior to the application of adhesive material.
6. The natural process of exfoliation of the epidermis limits the effectiveness of one application to about three weeks; on the plantar surface of the foot, over four weeks.

116 East Sixty-Third Street.

MACROCHEILIA *

FREDERICK B. MOOREHEAD, M.S., M.D.

AND

KAETHE W. DEWEY, M.D.

CHICAGO

Macrocheilia, or enlargement of the lip, is essentially a hypertrophy or hyperplasia, involving chiefly the lymph vessels. It is therefore generally classed among the lymphangiomas. Very brief and very few are the statements found in textbooks on pathology concerning this abnormal condition of the lips, and little space is generally given it in clinical reports and in journalistic literature dealing with lymphangiomas. It is chiefly since Wegner's¹ investigations on the subject that it

macrocheilia on record is one of a hemangiomatous macrocheilia, reported by Sonntag.³ It was associated with a hemangiomatous macroglossia. Cases have also been observed in which the proliferation involved chiefly the connective tissue. An entirely different and rare type of macrocheilia is represented by a few cases in which the enlargement was due to an abnormal development of the mucous glands of the lips. According to Fraenkel,⁴ they are either due to purely inflam-

Fig. 3.—Plaster cast before and after treatment.

matory processes, or are genuine, that is, congenital, abnormalities.

Macrocheilia is a purely clinical conception, as Eichler⁵ states, who defines the malformation as a persisting condition of a uniform swelling, equal in all dimensions. The lip appears twice, thrice and even six times as large as normal. The essential form is, in general, retained, but it is peculiarly clumsy and entirely out of proportion to the other parts of the face. The abnormality has been so marked in some cases that such a mouth has been compared to a snout or a trunk. A circumscribed lymphangiomatous enlargement of the lip is therefore not to be called macrocheilia, nor does any temporary swelling resulting from inflammatory processes belong to this group of malformation. A few cases, however, have been observed in which a true macrocheilia, that is, a persisting uniform enlargement of the lip, developed as a sequel of recurrence of erysipelas.

DEVELOPMENT OF MACROCHEILIA

Macrocheilia is generally congenital; but it may also be acquired. The collective name of lymphangioma, applied to the condition to which this malformation is accredited, includes a large variety of forms, which are difficult to separate into well defined groups. But the congenital form of macrocheilia, together with several similar congenital lymph angiomatous or hemangiomatous hypertrophies of the face and neck, constitutes a fairly well characterized group, namely, that of the tongue (macroglossia), the cheek (macromelia), the skin (nevus lymphaticus) and the palate and the neck (hygroma colli et cervicis congenitum). In the congenital form, the malformation may be present at birth; in these cases the same disproportion of the size of the lip to the rest of the face remains as the child grows. Or there may be a mere suggestion of the malformation in the new-born child, and the disproportionate development occurs later. This is sometimes observed in association with recurrences of inflammatory processes, especially in erysipelas. Generally, the condition appears soon after birth or in

Fig. 1.—A patient before operation.

Fig. 2.—Patient after operation.

has become customary to consider this condition as a lymphangioma or a lymphangiectasis. Sluys² calls it a lymphangiomatosis. The blood vessels, however, may be as much involved as the lymph vessels. Occasionally, the blood vessels alone are abnormally developed. One of the most remarkable cases of

earliest childhood. Instances in which it developed late in life are rare; in a case reported by Sonntag, the patient was 47 years old; Sluys reported macrocheilia in a woman, aged 54.

In women, the condition is apt to arise at the beginning of menstruation, during pregnancy or at the menopause. The development is rarely acute; generally it is slow, and in some instances interrupted by long intervals. In the cases in which the macrocheilia appeared late in life, the condition developed suddenly. One lip or both may be involved; macroglossia may be associated with it. In a few cases, alterations in the form of the jaw have been observed; the teeth are also sometimes involved. A remarkable case was one reported by Sonntag in 1914,² which occurred in a man, aged 47. The lower lip and the tongue were enlarged to such a degree that the patient was unable to bite or chew, or to keep the tongue within the mouth except by holding it back with the hand. The tumor was a hemangioma; by pressing down on the tongue or stroking backward, the size could be reduced almost to normal. This may be done with some lymphangiomas also—by pressure, the tumor may be greatly reduced. When the pressure is released, there is a return to the former size. The enormous amount of blood thus indicated greatly complicated the operation reported by Sonntag, which, however, was accomplished, giving satisfactory results.

TREATMENT WITH RADIUM

Successful treatment with radium was reported in 1914 by Sluys.² The patient was a woman, aged 54. The tumor was very large, of even consistency, and

well developed mustache, which the woman possessed, remained intact.

The abnormal growth in macrocheilia involves chiefly the corium and the subcutaneous tissue. The main feature is dilatation of the lymph vessels. A new formation of vessels is not always demonstrable; the

Fig. 5.—Completed dissection and method of closing wound with horsehair suture.

condition is more often one of lymphangiectasis. If the process progresses, the ectasis may develop into a cavernous lymphangioma. The connective tissue, which frequently proliferates simultaneously, is generally rich in lymphocytes and may contain elastic fibers and smooth muscle fibers. Not infrequently, the blood vessels are also abnormally developed. Sometimes blood is found in spaces which are clearly lymph spaces. This observation is explained by the fact that the blood vessels and lymph vessels are often very close together; the former sometimes actually seem to lie within the latter; the slightest injury may therefore lead to an exchange of the contents between lymph and blood vessels.

ETIOLOGY

As to the etiology of macrocheilia, several theories have been advanced, but a satisfactory and generally accepted explanation has not yet been given. Virchow's view is that the condition is due to some disturbance in the development of the branchial arches. This may be true in some instances; Eichler³ believes that in one of his cases there were evidences of such an origin. Nevertheless, we are still entirely ignorant as to the influence which produces the disturbance. Samter⁴ expresses the view that probably all congenital lymphangiomas, including those which develop at an early period of life, have an embryonic origin, which consists in the development of lymphoglandular tissue. They occur in the regions in which dermoids are found. Stasis of the lymph is to be considered as the immediate cause of the lymphangiectasis in macrocheilia; this has been explained as being due to obliteration of the lymph vessels in the deeper layers of the skin by proliferation of the endothelium, or, according to Rind

Fig. 4.—Method of opening lip for dissection of excessive lymph tissue.

not producing any pain. Ten days after the first treatment the tumor had completely disappeared. Sluys employed the gamma rays—which penetrate the deeper structure, leaving the outer tissues unaffected—with the result that no pigmentation occurred and a fairly

fleisch,⁷ to hyperplasia of the muscle fibers, impeding the lymph circulation. Wegner, in his classical work on lymphangiomas, discusses three ways in which the stasis of the lymph may be brought about: First, there may be occlusion of the regional, efferent lymph vessels, which may be produced either by a primary fault in the development (*vitium prima formationis*) or by thrombosis, or by compression and misplacement resulting from local processes of inflammation and scar formation. Secondly, there may be an active proliferation of the endothelium of the lymph vessels, in the course of which solid cell masses are formed. Between these endothelial cell accumulations, hollow spaces develop which, by opening into preexisting lymph vessels, become real, new lymph vessels. This constitutes a homeoplastic neoplasia. A probable third mode is that granulation tissue develops in a connective tissue matrix, and, indirectly, by secondary transformation of this tissue, new spaces containing lymph are formed. This is a heteroplastic neoplasia. Wegner is of the opinion that in the congenital form of macrocheilia, the stasis appears during the fetal period of life, the disturbance occurring in a region involving the lymph vessels; possibly the efferent lymph vessels are occluded because they are primarily not sufficiently developed. According to Borst,⁸ there may be at an embryonic period of development an excessive formation of lymph vessels, perhaps associated with a faulty connection between these and the rest of the lymph system, with the result of stasis and ectasis.

Microscopic examination of the tissue removed from a patient with macrocheilia revealed that the abnormal development involves the blood vessels to the same degree as the lymph vessels. Evidently, they are for the most part dilated capillaries, having only an endothelial wall. The blood vessels often have constrictions and ampulla-like dilatations; they are curved, or form cavernous sinuses. The lymph vessels and spaces surpass the blood vessels in size; they are very irregular in form, and many of them have, like the blood vessels, a cavernous appearance. Two or three may communicate with one another. They are lined with a continuous endothelial layer; sometimes the cells are separated; more rarely, spaces are found which have no cells. This separation of endothelial cells and the

more infrequent absence of cells are, of course, the result of the lymph stasis. By the increasing pressure, the thin wall is stretched, and the cells lie farther apart; they are flattened out and finally may disappear entirely.

The hemolymphangioma involves chiefly the corium and the subcutaneous tissue. There are also dilated blood and lymph capillaries between the muscle fibers in the deeper layer of the tissue. There is not a marked general proliferation of the endothelial cells; but interesting and noteworthy are the papillary cell proliferations extending from the wall into the lumen of the lymph vessels. Five or six such intravascular papillae are present in almost every section. These cell collections appear either as small elevations, closely adherent to the inner wall, in the form of darts or nodules, or as larger, globular or berry-like masses, which become pedunculated and finally are entirely

detached. They consist of proliferated endothelial cells and small round cells; flat endothelial cells are sometimes found at the periphery, forming a sort of outer lining.

As the process goes on, the proliferating cells assume larger forms; sometimes fusion of the protoplasm of several cells takes place. In the largest villi, regressive changes have set in; the protoplasm is disintegrated, and the nuclei have disappeared. These changes are always most marked in that portion which is nearest the vessel wall, while toward the lumen the cells are well preserved. Sometimes cell proliferations extend like bridges from one side

of the wall to the opposite one. These papillae occur only in lymph vessels. They are not thrombi; polymorphonuclear leukocytes are absent in them. The larger number of lymph vessels and lymph spaces are empty; in others there are masses of coagulated material, which is precipitated lymph. Sometimes, a finely granular, yellowish brown pigment is found within coagulated masses along the inner border of the vessel wall, sometimes also just outside the wall; there is no evidence that it is derived from the blood. These precipitated masses are the result of the stasis of the lymph. Wegner described them first and called them lymphthrombi; he observed all forms of transitions in the regressive changes. Cellular lymphthrombi, however, which he mentions, are not present in our sections; only rarely a polymorphonuclear leukocyte or a red cell is engulfed in the precipitated mass. Occasionally, an entire small vessel,

⁸ R. C. M. Pathologie Anatomie, I, A. 1910, page 111.

content and wall, is converted into one mass, resembling huge giant-cells; in some of them the nuclei of the proliferated endothelial cells have remained at the periphery, in others they are grouped eccentrically or lie in the center.

The blood vessels are, outside the normally existing arteries and veins, dilated capillaries, the walls of which are as thin as those of the dilated lymph vessels. They are recognized by the presence of blood. Sometimes, a few blood corpuscles are also found in lymph vessels. Their presence is easily explained. Lymph vessels and blood vessels lie close together; the latter seem sometimes to invade the former. Communication between blood and lymph vessels is not unusual in lymphangiomas. Through pressure from the continued stasis, the thin wall may be so overdistended as to yield at one point or another to the higher pressure from an adjoining blood vessel, and blood then passes into the eroded lymph vessel. Thrombi may form at these places, which close the opening; but in the course of regressive changes they may be canalized again. When several vessels communicate, there is generally proliferation of the endothelial cells at the place of confluence.

There is only a moderate degree of proliferation of the connective tissue, while there is a noteworthy increase of smooth muscle fibers. Infiltration with small round cells is present, more or less, throughout the corium. They collect especially around the vessels. There are regions in which the lymphangiectasis is in the background; here the tissue consists largely of lymphocytes and innumerable minute vessels. Here and there are denser collections of lymphocytes, which resemble lymph follicles. There are areas of small and large hemorrhages in all stages of regressive changes.

In the case of macrocheilia shown in Figure 1, there was a cavernous hemolymphangioma, which was probably of a congenital origin. The abnormal development did not consist of an angiectasis only, but obviously a new formation of blood and lymph capillaries had also taken place. An interesting feature was the papilla-like intravascular proliferations of the endothelial cells. Indications that they might be sprouts which develop into new lymph capillaries were lacking. A perceptible lumen was nowhere found. The regressive changes which they undergo also speak against such a supposition.

OPERATIVE TECHNIC

The operation for correcting macrocheilia is not difficult. Unless, however, it is intelligently performed, deformity may result. The lips are clamped with a lip-clamp to prevent hemorrhage, which is profuse. The mucous membrane is opened by two parallel incisions the entire length of the lip, and a small section of tissue is removed. By careful dissection, the excessive lymph tissue is removed until the lip has been reduced to normal. The wound is closed with a figure eight horseshair suture, the first loop closing the deep structures and obliterating dead spaces, and the second loop closing the mucosa. If horseshair is used in this fashion, buried sutures are not necessary, and scar formation is reduced to a minimum.

ABSTRACT OF DISCUSSION

DR. VILRAY B. BLAIR, St. Louis: Too often talks on the result of surgery of the face are merely descriptive of technic, and the result is sometimes not what you want. The question of this lymph enlargement is one of the most diffi-

cult things we have to deal with in surgery. I have always been held down a little bit, possibly, by the fetish of Butlin, that if you burn these things or irritate them, you possibly may get some reaction toward sarcomatous formation. I cannot say that I have ever seen it, but I have always thought it deserved some attention. I have tried radium. Other people have found it a success, but I have not had very good results. The way we have handled them is to pick out blocks of tissues where it could be done with the least possible deformity resulting. The whole thing appeals to me as one of the meanest conditions in surgery, unless you can take it out as a whole.

DR. M. I. SCHAMBERG, New York: The paper of Dr. Moorehead is interesting, and the most important part of the paper to my mind is the fact that he called attention to the differentiation between the two cases of macrocheilia and those cases where there is a localized hemangioma or hematoma within the lip, or other types of inflammatory disturbances of a transient character. Often, as the result of injury, the lip may swell temporarily with the absorption of the inflammatory products, or the blood which may have extravasated into the tissue. I have had a number of lip cases within the past ten or twelve years that were intensively interesting. One was in a member of my own family, an infant born with a large hematoma of the lip. This was readily removed with a very nice result. The great tendency is to remove insufficiently the amount of the growth in these cases of hemangioma. In the case of lymphangioma the growth is more nearly uniform, and the lip is enlarged throughout. It is important to differentiate between those cases in which there is a localized growth within the lip, those which are distinctly inflammatory or transient, and those in which there is a true hypertrophy. There is one other type of lip condition that sometimes resembles a macrocheilia and that is the so-called double lip, or what I prefer to call prolapse of the lip, which is much like the prolapse of the anus. These cases can be handled in very much the same way. I am fully in accord with the view that it is necessary during the operation to be sure that you have removed sufficient of the lip by approximating the edges, and that the best results are not seen within a week or two after the operation. It takes a little time for the lip to reestablish the disturbed circulation, and to cause absorption of the edges of the wound, which are rather stiff as the result of the operation.

DR. THOMAS L. GILMER, Chicago: It seems to me that the term macrocheilia is not the best name for the conditions described. It means simply an enlarged lip, and since we have so many different conditions which cause enlarged lips, we should be more specific in differentiation. I have had better success in the treatment of enlarged lips due to prolapse of the mucosa than in cases of lymphangioma of the lips. I have had but one case of the latter, and in this, the success was not as good as I had hoped for. I dissected out the enlarged lymphatics in the lip as thoroughly as it seemed desirable, even making the lip smaller than it should be, but in the course of a few months, the lip was enlarging again. I have had the same fears as expressed by Butlin and also by Dr. Blair today of the possibility that changes to malignancy may result from surgical interference.

DR. FREDERICK B. MOOREHEAD, Chicago: Dr. Blair has raised the question of malignancy, and it is interesting to note that a careful review of the literature does not reveal a single case of malignancy in connection with the lesion under discussion. The use of radium in these cases is more or less experimental as it is elsewhere. I have not had enough experience in the use of radium to make any definite statement about its application.

Medicine as a Business. If business men, looking at the practice of medicine as a "business proposition," have seen the advantage of organization, may not the time come when medical men who see the practice of medicine as a high and noble profession will grasp the opportunity to join with one another in developing efficient centers of group medicine? —M. M. Davis, *Am. J. Pub. Health* 9:361, 1919.

DIAGNOSIS AND TREATMENT OF DISEASES OF THE GALLBLADDER AND BILIARY DUCTS

PRELIMINARY REPORT ON A NEW METHOD

B. B. VINCENT LYON, A.B., M.D.

Chief of Clinic, Gastro-Enterological Department, Jefferson Hospital;
Attending Physician, Methodist Episcopal Hospital

PHILADELPHIA

Two years and a half ago a paper was published by S. J. Meltzer¹ of the Rockefeller Institute which carried at the end this footnote:

In experiments with magnesium sulphate I observed that the local application of a 25 per cent. solution of that salt on the mucosa [of the duodenum] causes a completely local relaxation of the intestinal wall. It does not exert such an effect when the salt is administered by the mouth, that is, when it has to pass through the stomach before it reaches the intestines. The duodenal tube, however, apparently has reached an efficient practical stage. I make, therefore, the suggestion to test in jaundice and biliary colic the local application of a 25 per cent. solution of magnesium sulphate by means of the duodenal tube. It may relax the sphincter of the common duct and permit the ejection of bile, and perhaps, even permit the removal of a calculus of moderate size wedged in the duct in front of the papilla of Vater. Twenty-five c.c. of the solution as a dose for an adult will bring no harm. For babies the dose should not exceed 4 c.c. The procedure could be developed into a practical useful method.

This simple footnote served as an inspiration for a clinical experimental study on human beings, at first with magnesium sulphate and later with other solutions. I believe that the experimental observations on animals, as conducted by Meltzer, have borne fruit and have opened up a new method of diagnosing diseases of the gallbladder and of the biliary ducts.

This study, conducted for fifteen months in France, on men of the U. S. Navy in Base Hospital No. 5, for six months in the clinic of the Jefferson Hospital, in the wards of the Methodist Episcopal Hospital, and in the author's private practice, is a study which has now been made of more than 100 cases, with a total of nearly 1,000 observations. We have proved and are now in a position to demonstrate that Meltzer's assumption is correct—the instillation directly into the duodenum of magnesium sulphate, in solution of various strengths and in various amounts, is followed shortly afterward (within from two to fifteen minutes in most cases) by the evacuation of bile into the duodenum, which can be aspirated by the syringe and the vacuum bottle. Magnesium sulphate appears to be a chemical messenger (hormone) which has the ability not only to relax the sphincter of the common bile duct and thereby drain the bile in the ducts, but also, simultaneously, to cause the gallbladder to be compressed and to empty its contents. Our observations have convinced us of the soundness of the theory of Meltzer's law of contrary innervation as applied to the gallbladder and biliary passages.

Magnesium sulphate, however, is not the only chemical excitant which is capable of producing this action of the biliary apparatus. Our studies have shown that there are others which are capable of a similar action and which will be reported later on. The procedure has gradually taught us that it is possible to segregate and study, cytologically and bacteriologically, not only

bile from the gallbladder, but also bile freshly secreted from the liver itself. It has taught us that we can differentiate within reasonable certainty between diseases of the various components of the biliary system, that is, that we can make a differential diagnosis between cholecystitis, cholelithiasis and choledochitis in a more scientifically accurate manner than by any other method yet advanced.

CAUSE OF INFECTION

For some years we have been aware that the gallbladder or the bile ducts may become infected with pathogenic organisms through several routes: by ascending infection of the common duct directly from the duodenum; by infection by way of the portal vein, and possibly by infection directly from the systemic circulation. All these theories as to the portal of entrance can be attractively argued, but we have been impressed in our study by the frequency with which infection by the avenue of direct ascending infection from the duodenum can be proved. We believe that in the larger number of instances the sequence of events is: a primary source of infection in the mouth (gums [pyorrhea alveolaris]; teeth [apical abscesses]), nasal sinuses and respiratory tract (lungs [pneumonia, especially of the lobular, mixed infection type], capillary bronchitis, etc.), and bronchial tree (simple catarrhal or purulent—large tube—bronchitis), with the swallowing of infected saliva, which sets up, under favorable circumstances, an infective gastritis (this can be proved) or which passes by the stomach, leaving it unharmed, to produce an infective duodenitis (which can be proved) and, ascending thence through the ampulla of Vater, infects the common duct and obtains final lodgment in the gallbladder. The gallbladder, once infected, provides an excellent culture medium for continued bacterial development.

Recognition of this chain of infection was forced home on me by observation, in French waters, of sixteen cases of catarrhal jaundice in American sailors, whose gastric, duodenal and biliary secretions were studied, and the patients treated, by the method herein outlined. Parenthetically, it may be said that the course and duration of these cases of catarrhal jaundice was shortened from an average of thirty-five days in nine cases (treated in the usual symptomatic manner, with bed rest, restricted diet, cholagogues and hexamethylenamin) to an average of seventeen days in seven cases in which topical treatment of the duodenum was undertaken. These cases will be reported later on.

METHOD OF ASPIRATION

After considerable experimenting, we are using at present this method of studying suspected gallbladder and biliary duct cases:

The patient is examined in the fasting stomach state; the mouth is rinsed thoroughly with any good antiseptic solution. We prefer potassium permanganate, 1 grain to 2 ounces of water, followed by a rinse with a weak solution of zinc chlorid. A sterile duodenal tube, fitted with any one of the later modifications of the original metal tip,² is passed into the stomach; the fasting gastric residuum is aspirated into a sterile vessel, is measured and grossly observed for consistency, mucus, etc., and then is cultivated and studied chemically for acidities, for bile and for occult blood.

² All the special apparatus used in this method will be fully described in a later article.

Microscopically, we pay especial attention to *endogenous* epithelium, to polymorphonuclear leukocytes, with or without digested protoplasm, and to the general amount and the morphology of the bacterial flora, differentiating between these and findings which are similar but of *exogenous* origin. With care and the enlargement of personal observation, this differentiation can be made with a reasonable degree of certainty, and it is later checked up by other methods. The stomach is then thoroughly rinsed and the patient is given a glass of water to drink while *slowly* swallowing the tube to the duodenal point, and while lying on the right side, with a pillow or a sandbag elevating the hips.

The tube usually passes into the duodenum within fifteen to forty-five minutes. When it has done so the fact can be determined by the duodenal "tug," the character of the aspirated fluid, and the failure to recover immediately by vacuum aspiration material (water, broth, etc.) which the patient swallows by mouth. Difficulty is occasionally encountered in entering the duodenum because of vagotonic states, or local pylorospastic states (a reflex from duodenal ulcer, cholecystitis or chronic appendicitis) which can be overcome by an injection of atropin sulphate or by several days' use of belladonna or benzyl benzoate. Once it is sure that the tube is in the duodenum, a barrelful of air is introduced from a 1 ounce capacity syringe to balloon out the duodenal walls from the metal tipped tube (to prevent traumatism of the duodenal mucosa); a connection is made with the *first* sterile aspirating vacuum bottle, and gentle aspiration of the duodenum is begun.

In the fasting duodenal state, and when the physiologic condition is normal, the sphincter of the common bile duct should be closed, and the duodenal contents should be bile free, pearly gray, of syrupy and stringy consistency, fairly transparent, and should have a relatively small amount of flocculent or flaky sediment. In states of duodenitis the gross appearance, the microscopic sediment and the chemical tests differ widely from the normal. When bile is found in the fasting duodenum in sufficient quantities to be grossly visible, we believe that there is either a disturbed physiologic condition (following the analogy of Meltzer's law of contrary innervation) or a pathologic lesion of group organs physiologically related to this intestinal zone.

The first bottle is detached and with its contents of aspirated fluid set aside for bacteriologic, cytologic and chemical examination. We now introduce, by means of a sterile syringe or by the gravity method from a sterile container, from 50 to 100 c.c. of a sterile, 25 per cent. saturated solution of magnesium sulphate, and connect up the tubing to the *second* sterile aspiration bottle and start gentle aspiration. Usually, within from two to ten minutes, bile begins to be recovered, staining light yellow the magnesium sulphate solution still in the duodenum. When the color deepens to a pronounced yellow, the material already collected in the second bottle is decanted into a sterile glass container; the bottle is reattached, and biliary drainage is continued.

It will be observed that the bile flows intermittently, somewhat after the manner in which urine is secreted from the ureters into the bladder in patients in whom cystoscopy and catheterization of the ureters have been performed. Especially is this intermittent flow observed after the bile already in the ducts and in the

gallbladder has been drained and bile is being collected as it is secreted from the liver capillaries. We believe that the first bile aspirated is the bile present in the bile ducts—probably only the common duct—because it is lighter yellow, more likely to be transparent, and much less mucoid than the bile seen later. This first bile may be from 10 to 20 c.c. in amount and may require from one to three minutes to aspirate, when a sudden transition appears (seen first in the glass window of the tube) and the bile becomes darker, more viscid and more concentrated and, in normal gallbladders, remains transparent, but is more of a molasses yellow. We believe this type of bile to be that stored up in and delivered from the gallbladder, and when it appears first in the glass window the second sterile bottle is detached and replaced by a *third* sterile collecting bottle into which the bile is allowed to flow until all of this darker bile (more viscid, transparent or turbid) has been collected and is being replaced by a lighter yellow, thinner and usually transparent bile which is aspirated much more slowly and intermittently, and which we believe to be bile freshly secreted from the liver. When this second transition appears, the third bottle is detached and a *fourth* sterile bottle attached to collect the liver bile.

Thus, we believe we are able to collect separately bile from different parts of the biliary apparatus and, by receiving them in separate containers, to study each sample chemically, bacteriologically and cytologically. We have found the bile from the gallbladder to vary in amount from 30 to 100 c.c.; in one case the amount was 166 c.c., the largest quantity in our experience. We believe that the high normal probably should not exceed 75 c.c. (2½ ounces). This variation in amount is to be expected, and would depend somewhat on the length of time since the gallbladder had last emptied itself, partially or completely, in response to normal digestive needs; on mechanical factors that prevent its ready emptying of itself unassisted, such as inflammatory adhesions, or thick, viscid, sluggishly flowing bile caused by catarrhal conditions of the gallbladder; or the variation may be dependent on the tonicity of the gallbladder musculature, for it is readily conceivable that in overdistended, dilated gallbladders the muscle wall has been so stretched as to possess insufficient tone to propel the contents easily through the cystic and into the common duct.

THE BILE IN PATHOLOGIC CONDITIONS

In pathologic states of the gallbladder, the appearance and the character of the bile are quite different from those in the normal bile described above. We have seen these types:

A. *Choledochitis*.—In choledochitis, the bile first collected is definitely pathologic. It is more viscid, with an excess of flaky mucus, is usually turbid and usually "off" color; cytologically, it contains pus cells enmeshed in mucus, epithelial cells and, occasionally, red blood corpuscles; bacteriologically, cultures may show pathogenic organisms. This type has been encountered in choledochitis with cholecystitis. We have frequently seen choledochitis alone in "simple" catarrhal jaundice, and, in these instances, the usual picture has been of an infection of a lower grade than when the gallbladder is also involved.

B. *Cholecystitis*.—In cholecystitis without choledochitis, the first bile collected is relatively normal, grossly and cytologically, and culturally does not con-

tain pathogenic organisms. But the second bile is grossly pathologic; it is more viscid than normal gall-bladder bile; it is turbid, with a flaky or stringy mucus; cytologically it will show inflammatory elements, pus cells, red blood cells (occasionally) and desquamated epithelium, and, bacteriologically, cultures will show pathogenic organisms. Thus far, we have "recovered" streptococci of various strains, staphylococci, *Bacillus pyocyaneus*, *B. typhosus* and *Micrococcus catarrhalis*. In some cases the cultural findings have been negative, but the catarrhal elements have been pronounced. The viscosity, color and general appearance of the bile in pathologic conditions of the gallbladder will alone suggest the diagnosis. The color varies from a deep, golden yellow, to a dark, molasses yellow, transparent or turbid; to a light, mustard yellow, always turbid, and occasionally streaked with slimy mucus of a greenish color; to various shades of green or greenish black, and, in one case, was of such a tarry consistency as to make aspiration very slow and difficult.

C. Cholelithiasis.—In cholelithiasis we find the evidence of cholecystitis, but in two instances we have noted in addition that the bile contained a sediment that was "gritty" or sandlike in consistency, which was seen, microscopically, to be made up of crystals of bile salts. In one case, that of a Filipino mess-attendant with jaundice, we succeeded, by the local use of magnesium sulphate, in recovering three small, faceted gallstones. Later, this patient was operated on by Dr. Robert G. Le Conte, who found and removed one very large calculus, about the size of an English walnut, which was blocking an enormously enlarged common duct, and several small stones, still remaining in the gallbladder.

We have yet seen no instances in which bile freshly secreted and collected from the hepatic ducts after the gallbladder bile has been expressed has given us positive bacteriologic or cytologic findings suggestive of an infection involving or originating in the liver. It may prove possible later to submit differential proof of such a state. It is very likely that the bile freshly secreted from the liver carries a higher bacteriologic potentiality than that from any other part of the biliary apparatus.

The demonstration of biliary stasis (due primarily to functional disorders of the gallbladder, if there are such, and shown in the recovery of bile that is not pathologic beyond being increasingly viscid and concentrated) may, in addition to the organic conditions described, help us better to understand the primary causes of conditions we now call "biliousness" or "bilious attacks."

FUTURE POSSIBILITIES

So much now for the question of diagnosis by this method. In a subsequent paper I shall attempt to enlarge this sketchy preliminary report and to contribute further to our knowledge of the physical properties of bile in its relation to biliary diseases, and to show that there are chemical messengers, other than magnesium sulphate, that will stimulate the flow of bile.

This method of direct access to the biliary apparatus opens up a new field of rational medical treatment for diseases of the gallbladder and of the bile ducts, and in a paper soon to be published I shall report our therapeutic experiences of the past two and a half years.

Considerable success has been achieved in the treatment of cholecystitis, choledochitis, catarrhal jaundice

and infective duodenitis by this method of direct medical drainage of the biliary apparatus, and direct disinfection of the duodenum and intestine by the use of various germicidal solutions.

THE INFLUENCE OF INFLUENZA ON MENSTRUATION, PREGNANCY AND PUERPERIUM*

FERNANDO CALDERON, M.D.

Director, Philippine General Hospital; Professor of Obstetrics and Dean,
College of Medicine and Surgery, University of the Philippines

MANILA, P. I.

During the first influenza epidemic of 1918, I observed two cases of premature labor in the course of influenza in the Philippine General Hospital. The patients were at first admitted to the medical department and were later transferred to the department of obstetrics. I could not attribute the interruption of pregnancy in these two cases to any causes other than influenza and quinin. Quinin was considered as a possible cause, because the patients, while in the medical department, were given massive doses of the drug which, according to various authors,¹ strongly stimulates the contraction of the uterus, and is even credited with producing abortion.

TABLE 1.—INTERRUPTION OF PREGNANCY DUE TO INFLUENZA
IN TWENTY-SEVEN CASES

No. of Cases	Month When Pregnancy Was Interrupted
2	Within the fourth
2	Between the fifth and the sixth
4	In the seventh
19	Between the eighth and several days before the expected date of confinement

During the three months beginning with October of 1918, when the largest epidemic of influenza broke out in the Philippine Islands, thirty-six cases of influenza were admitted to the department of obstetrics. In nine cases, the disease was contracted in the course of the puerperium, and in the remaining twenty-seven it occurred as a complication of pregnancy. The disease was not complicated by bronchopneumonia or lobar pneumonia in five of the former and in seven of the latter cases.

Quinin was not used with any of the twenty-seven pregnant patients, but in spite of this precaution, pregnancy was interrupted even in seven cases in which influenza was not complicated by bronchopneumonia or lobar pneumonia. The elimination of quinin in the treatment limits the possible causes of the interruption of pregnancy in these cases to influenza and makes it highly probable that the disease was the exciting cause of premature labor in my first two cases.

This observation does not, therefore, coincide with the finding of Bar and Boullé,² and of Ahlfeld.³ It confirms the conclusion of Felkin⁴ and Muller⁵ that influenza exerts a very pernicious influence on pregnancy, and shows that this it does independently of

bronchopneumonia and lobar pneumonia which frequently complicated the disease during the last epidemic.

A question of scientific interest is, How is the interruption of pregnancy produced by influenza? Is pregnancy interrupted by the cough and asphyxia that are usually associated with the disease, or does the toxin of the Pfeiffer bacillus act as an echolic? The fact that coughing and asphyxia were not prominent symptoms in some of the cases tempts me strongly to believe that the toxin acts directly on the uterus. Its selective action on this organ is further supported by the early appearance of menstruation when the women contracted the disease. I have frequently observed this effect of influenza in the last epidemic.

TABLE 2.—HIGH MATERNAL MORTALITY OF INFLUENZA DUE TO BRONCHOPNEUMONIA AND LOBAR PNEUMONIA

	Cases with Broncho- pneumonia		Cases with Lobar Pneumonia		Cases with- out Com- plications		Total Number of Deaths
	Fatal	Non- Fatal	Fatal	Non- Fatal	Fatal	Non- Fatal	
Influenza in pregnancy.....	0	3	13	4	0	7	13
Influenza in puerperium....	2	0	1	1	0	5	3

The maternal mortality of influenza in my series of thirty-six cases was excessively high. This was due exclusively to bronchopneumonia and lobar pneumonia, because without any of these complications the disease did not cause a single maternal death. In this series the bronchopneumonia complicating the puerperium, and the lobar pneumonia in pregnancy, were fatal in 100 and 76.4 per cent., respectively. The frequent incidence of lobar pneumonia and its high mortality make influenza a grave complication of pregnancy. According to the record of the Philippine General Hospital for 1918, it was more fatal than eclampsia or malaria and typhoid fever in pregnancy.

Influenza also exerted a deleterious effect on the fetus. Among the twenty-seven pregnant women, I

TABLE 3.—MORTALITY OF INFLUENZA, ECLAMPSIA, MALARIA AND TYPHOID FEVER IN PREGNANT PATIENTS ADMITTED TO THE PHILIPPINE GENERAL HOSPITAL IN 1918

	Influenza	Eclampsia	Typhoid Fever	Malaria
Mortality	48.1%	41.1%	16.6%	0%

had one case of hyperpyrexia in a newly born baby, and seven deaths. The latter includes cases of intra-uterine deaths and those which were born within the period of viability and died several hours after birth.

SUMMARY

1. Influenza exerted a pernicious influence on pregnancy. This pernicious influence was direct and independent of the bronchopneumonia and lobar pneumonia complicating the disease.
2. Influenza caused untimely appearance of menstruation.
3. Lobar pneumonia complicating influenza was responsible for the high mortality of this ordinarily benign disease in pregnancy.
4. Bronchopneumonia produced by influenza caused 100 per cent. mortality when it occurred in the course of the puerperium.
5. Influenza caused a deleterious effect on the product of conception.

THERAPEUTIC APPLICATION OF THE ALTERATION OF BRAIN VOLUME

BY THE INTRAVENOUS INJECTION OF GLUCOSE

RUSSELL L. HADEN, M.D. (DETROIT)

Lieutenant, M. C., U. S. Army

CAMP LEE, PETERSBURG, VA.

The brain and spinal cord lie within a space of fixed capacity formed by the closed cranium and the spinal canal. The pressure within the meninges is determined by two factors, the amount of cerebrospinal fluid present and the volume of the brain. The removal of spinal fluid by lumbar puncture is commonly employed in controlling intracranial pressure in a large number of conditions. If there is a very marked increase in the bulk of the brain, however, the intracranial pressure may still be high, even after the maximum amount of spinal fluid has been drained off. It is also true that the withdrawal, when the high pressure is due to the increased volume of the brain, may cause a herniation of the base of the brain through the foramen magnum, with resulting collapse and death.

The one medical condition in which we are most interested in intracranial pressure is cerebrospinal meningitis. The marked increase in pressure in this disease is certainly one of its most serious aspects. There is an increase both in the amount of spinal fluid and in the direct volume of the brain. The increased pressure is often the factor determining the outcome of the disease.

It has long been recognized that lumbar puncture and drainage of the spinal fluid cause, alone, a marked decrease in the mortality rate. This is unusually well shown in the recent report by Olitsky¹ of an epidemic in China in which only a small amount of immune serum was available for treatment. In 104 cases, in which no treatment of any kind was given, the mortality was 84.6 per cent.; in 346 cases in which lumbar puncture and drainage of the spinal fluid were the only treatment, only 54.1 per cent. of the patients died. The removal of bacteria and toxic material must certainly have had some effect, but it seems most probable that the greatest good was due to the necessary fall of intracranial pressure resulting from the withdrawal of spinal fluid.

The power to control the volume of the brain should be of the greatest help in the treatment of meningitis. The spinal fluid removed must be replaced, in part at least, by immune serum, thus nullifying the good effects of the reduced pressure resulting from the removal of the fluid. In those cases of meningitis in which patients develop block, either at the base of the brain or at some point along the spinal cord, they quickly show the effect of increased intracranial pressure, and we have had no way of decreasing the pressure except by occipito-atlantoid puncture.

Recently, some experiments have been reported by Weed and McKibben² which show that the bulk of the brain can be controlled by a change in the concentration of certain elements in the blood stream. These observers have shown that the intravenous injection of hypertonic solutions of certain electrolytes and

1. Olitsky, P. K.: Experiences with a Recent Epidemic of Meningococcal Meningitis Among a Chinese Civil Population, *Arch. Int. Med.*, **23**: 350 (March) 1919.

2. Weed, L. H., and McKibben, P. S.: *Am. J. Physiol.*, **18**: 512 (May) 1919.

crystalloids causes a transient rise in the pressure of the spinal fluid, followed by a marked fall, which persists for a considerable period of time. On the other hand, the use of hypotonic solutions of the same substances causes a persistent rise in the intraspinal pressure. The injection of isotonic solutions causes no change in pressure.

The substance of election for intravenous administration in this connection is glucose. This can be used in very concentrated form, is cheap, and is not toxic. In addition to its use for changing the osmotic value of the blood, it is utilized by the tissues as a food, and also acts as diuretic. Litchfield¹ has emphasized the value of glucose administered intravenously in various diseased conditions. He shows that it combats dehydration, supplies energy and spares nitrogen. It seems probable that the immediate effect produced by the intravenous administration in the cases reported by Litchfield was due to the relief of cerebral edema and to the consequent decreased intracranial pressure brought about by the hypertonic solution.

Case 1, recorded below, is reported because the intravenous injection of a 25 per cent. glucose solution was probably a factor determining the outcome. And the vital thing was presumably the decrease in the intracranial pressure brought about by a change in the bulk of the brain.

We have used a 25 per cent. solution of glucose, but a 40 per cent. solution can be used perfectly well. Any pure glucose may be used. It should be made up in freshly distilled water and autoclaved or boiled. It is not necessary that a fresh solution be made up each time it is given. A stock solution will keep a considerable length of time. The injection should be made slowly, so that one hour is consumed in administering 250 c.c. of a 25 per cent. solution.

The first case reported was the last case of epidemic meningitis in which treatment was given at this hospital. We had planned, if other cases occurred, to treat them as a routine with glucose solution; but we did not have the opportunity. We suggest as a plan of treatment the intravenous injection of 25 per cent. glucose solution every twelve hours, from the onset of the disease until there is no longer any evidence of increased intracranial pressure, these injections to be in addition to the specific treatment, of course. If immune serum is given intravenously, the glucose solution may be given at the same time.

REPORT OF CASES

CASE 1.—A man, aged 21, white, admitted to the hospital, February 10, for epidemic cerebrospinal meningitis, was very ill from the onset. He at first improved under treatment, and was given 485 c.c. of immune serum intraspinally and 300 c.c. intravenously. February 21, the spinal fluid, which up to this time had flowed freely, could be obtained only drop by drop, a total of 5 c.c. being obtained. The rigidity of the neck increased, and the patient became irrational and incontinent. The next day he was in coma, and had epistaxis, rapid stertorous respiration and an irregular, rapid pulse. It did not seem possible that he could live more than a few hours. He was given 50 c.c. of immune serum, with 200 c.c. of 25 per cent. glucose solution, intravenously. There was very marked improvement. The next day he was given a total of 550 c.c. of glucose solution without serum. He became rational and made an uneventful recovery without further treatment of any kind.

¹ J. Litchfield, *Ann. Surg.*, 1918, 67: 141-142. ² J. Litchfield, *Ann. Surg.*, 1919, 70: 141-142.

In conditions other than meningitis, cases have been observed in which the intravenous administration of glucose has evidently had a direct cerebral action. In severe toxemias with marked general depression, a cerebral edema of varying degree is likely to develop. In the following case the abrupt change in the mental condition of the patient during the course of glucose administration could hardly be due to other than a change in the brain tissue.

CASE 2.—A man, aged 22, white, was admitted to the hospital, July 14, 1918, for measles. His temperature on admission was 103.3, pulse 88, and respiration 20. The examination of his lungs was negative. He coughed excessively, but showed no signs of a localized infection until the 18th, when there was a pulmonic consolidation at the right base. The same night the patient became delirious, and remained so the next day. On the 21st he lay in bed in a stupor, and would not answer when spoken to. The signs in his chest had become very diffuse. It did not seem possible that he could recover. His temperature had continued high from the onset until the 18th, but on the 19th and 20th was subnormal. His pulse was recorded as above 100 only once, and the respirations averaged 20. The afternoon of the 21st, as a last resort, he was given 300 c.c. of 25 per cent. glucose solution intravenously. After the injection had proceeded for one hour, he began to arouse, and by the time the injection was finished he was clear mentally, was oriented and answered questions readily. He made an uninterrupted recovery except for an intercurrent otitis media. He had no further treatment.

SUMMARY

1. Increased intracranial pressure is a very important factor in certain diseases, especially meningitis.
2. The alteration of brain volume of intravenous injection of hypertonic glucose solution can be made use of to control the pressure.
3. The intravenous injection of 25 per cent. glucose solution seems advisable as a routine measure in the treatment of meningitis.
4. In the two cases reported, the direct cerebral action of the glucose seems demonstrated.

HORSE ASTHMA FOLLOWING BLOOD TRANSFUSION

REPORT OF CASE

MAXIMILIAN A. RAMIREZ, M.D.

NEW YORK

Although the experimental demonstration of passive anaphylaxis has been clearly established by Nicolle, Otto, Friedmann, Richet and others, I wish to call attention to its importance in actual practice and suggest the necessity of including, in the routine examination of a prospective donor for blood transfusion, questions relative to the various anaphylactic manifestations.

REPORT OF CASE

H. T., man, aged 35, waiter, white, born in Greece, who had been five years in this country, underwent blood transfusion for primary anemia. He had never had asthma, hay-fever, bronchitis, urticaria, angioneurotic edema, or any other condition which might indicate a hypersensitiveness to some foreign protein. The family history was negative.

Two weeks after receiving 600 c.c. of blood, the patient left his home and went for a carriage ride in Central Park; almost immediately on entering the open carriage, he experienced some difficulty in breathing which within five minutes developed into a definite, clear cut attack of bronchial

asthma. The patient returned to his home, where a physician administered epinephrin hypodermically, bringing the paroxysm to a rapid end. That evening he coughed considerably, but feeling quite well in the morning, ventured for a short walk in the park. He was again seized with a severe attack of asthma.

It was after this attack that I first saw the patient and tested him against a large number of food and bacterial proteins, pollens, etc., with negative results, finally, however, obtaining a positive reaction to horse dandruff, measuring 1.5 cm. in diameter and reacting as high as a 1:20,000 dilution.

On learning of the transfusion which occurred but two weeks previously, and his negative previous history, I located the donor, who readily admitted being subject to a persistent and long-standing asthma and bronchitis. On testing the donor I obtained a reaction to horse dandruff measuring 6 cm. in diameter, and reacting as high as a 1:50,000 dilution.

COMMENT

1. The transmission of anaphylactic or reaction bodies should be borne in mind in choosing a donor for blood transfusion.

2. The presence of these "anaphylactic bodies" in the donor's blood caused no untoward effects on the recipient during or immediately following the transfusion.

3. This phenomenon did not occur in another patient to whom this donor had previously given blood, although a larger quantity of blood was injected (800 c.c.).

GENERAL HEALTH ACTIVITIES AND THEIR EFFECT ON TUBERCU- LOSIS MORTALITY*

GEORGE THOMAS PALMER, M.D.

SPRINGFIELD, ILL.

In preventive medicine, it is generally assumed that the discovery of the causal organism and the means of transmission of a communicable disease will be followed by a definite reduction in its prevalence and mortality, and that this reduction is greatly increased by an intensive campaign of popular education. This has been our experience with typhoid fever, yellow fever, malaria, diphtheria and other diseases, and it was the experience contemplated in dealing with tuberculosis. It has now been almost forty years since the identification of the tubercle bacillus, and almost thirty years since the first organization was created to combat the disease by means of popular education. For fifteen years that educational campaign has been intensified by the National Tuberculosis Association, which, with its affiliated societies, has become the largest and strongest extragovernmental health agency the nation has ever known. It is interesting at this time to consider what progress has been made in dealing with this most widespread of diseases and to attempt to determine, if possible, the means by which the very striking results have been accomplished.

Experience has taught us that tuberculosis cannot be measured by the standards which apply to other contagious and infectious diseases. The attempts to develop preventive and curative vaccines or serums from the

tubercle bacillus, such as we have produced in diphtheria and typhoid fever, have resulted in failure and disappointment. We have been forced to conclude that active tuberculous disease is not the result of a simple infection. Likewise, our efforts to control the disease by the restriction of public spitting, based on the fact that bacilli are commonly found in the sputum, have not given results which inspire any high degree of confidence. Tuberculosis has resisted our efforts to deal with it as a simple question of infection or contagion.

The relationship between infection and disease has been shown to be very remote. It is accepted that acute tuberculosis is not caused by any single organism acting alone. Dormant infection is so general that perhaps 80 per cent. of adults may be classified as "tuberculosis carriers." The development of the disease, after infection, is dependent on some factor or factors which reduce individual resistance, and these factors are to be found in every phase of the social life of the individual or of the community. Obviously, in the light of our present knowledge, victory over tuberculosis cannot be expected to result from warfare against the tubercle bacillus, however thoroughly that warfare may be conducted. Our present belief must be that success will come through our learning how to live with the tubercle bacillus rather than in striving to avoid initial infection.

I do not mean to convey the idea that we should abandon in any way the means we are now employing to prevent the spread of infection. Open cases should be isolated, coughing and spitting should be restricted, and increased pains should be taken to protect children from contact. I am profoundly impressed that by these means alone we shall not master the disease, and I am frankly doubtful if such means have been the important factors in achieving the success which has crowned the efforts of tuberculosis agencies in the past.

As to the success in the past, there can be no doubt. During the twenty years following the establishment of the first volunteer tuberculosis association, tuberculosis mortality decreased from 238 per hundred thousand of population to 166 per hundred thousand, or a decrease of 30.25 per cent., while a comparison of five-year periods during the past fifteen years shows a tuberculosis decrease of 22.2 per cent.—a more gratifying showing than that of any other communicable disease for which science had not provided a specific preventive, with the single exception of scarlet fever. With such a showing, the battle against the germ, which has characterized our avowed program in the past, seems to have fully justified itself.

But, a further observation of statistics causes us to become somewhat skeptical. During the twenty years from 1872 to 1891, the twenty years preceding the nation-wide educational movement and including ten years preceding the discovery of the tubercle bacillus, the mortality from tuberculosis decreased from 339 per hundred thousand of population to 245 per hundred thousand, or a decrease of about 27.5 per cent. In fact, Hoffman has pointed out, from such statistics as were available, that tuberculosis mortalities have steadily decreased for a period of over a hundred years, from 1812, when the rate in New York, Boston and Philadelphia was close to 450 per hundred thousand. This steady decrease in mortality, which had assumed interesting proportions years before the discovery of the bacillus, obviously cannot be attributed to the battle against the germ, and yet it seems readily

* Read before the Section on Preventive Medicine and Public Health at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

explainable and in perfect harmony with our present conception of the tuberculosis problem.

It is now generally agreed that tuberculous disease in the adult is usually due to childhood infection and that infection may remain relatively harmless throughout life unless the resistance of the individual is lowered. In short, tuberculous disease is the result of infection plus some other factor of lowered vitality or impaired health. Hence, the causal factors of tuberculous disease become myriad in number and every factor which tends to promote individual or community health becomes a definite factor in the prevention of tuberculosis. With this idea in view, we can reasonably account for the decrease in tuberculosis mortality, extending throughout the past century and assuming more gratifying proportions during the past few decades.

For a hundred years living conditions have steadily improved. Means of cleanliness have become readily available, fear of fresh air and night air have been abandoned together with our more absurd superstitions. Sewage disposal, water supply, safe milk and food supplies, ventilation and basic factors in health have gradually come to receive serious consideration. Childhood, the crucial point in health control, has been safeguarded by better obstetrics, better care of mother and infant and more recently by school sanitation and health activities among children based on the sane doctrine that sound bodies are as essential as cultivated minds.

Intelligent efforts in the prevention and suppression of communicable diseases—some of them notorious forerunners of tuberculosis—have made a decided impression on the mortality of the disease, as have activities in the field of housing, the prevention and relief of poverty, and other kindred health and social movements.

Thus, it appears that improved personal and community life, and general health and social activities which have gradually gathered momentum during the past century, have had more to do with reducing the tuberculosis death rate than the attack we have made on the bacillus. In fact, I am ready to believe that the improvement of general health through better milk supplies has done as much to stay the ravages of tuberculosis as anything we have done to control bovine infection, and that the effect of the general improvement of housing has been more far-reaching than our efforts to prevent disease by supervision of premises infected by the tubercle bacillus.

In attributing this gratifying showing in reduced tuberculosis mortality to the efforts made in general health, and social fields, we must not infer that the antituberculosis organizations have in any way failed. In fact, national, state and local tuberculosis associations have not only done their part in their own special field, but they have contributed to general health to an astonishing extent. In thousands of instances, these tuberculosis associations have been the pioneers in all health activity and, while they have placed proper emphasis on their own problem, which had been so long neglected, they brought with them the first public health nurses, the first child-welfare work and the first popular interest in health which served to stimulate activities in other lines, and to strengthen the hold of the governmental agencies on the public. If their policy of a battle against the germ was narrow, it was no narrower than that of others in a day of bac-

teriologic enthusiasm, and their practical performance has been big and broad and helpful.

In conclusion, I should like to have it understood that I am dealing with only one phase of a tremendously big subject; that I am questioning, as every student is questioning, the various factors which have played a part in the most complex of medical and social problems, and that I do not minimize the importance of the special tuberculosis activities or the unquestioned good which has resulted from such agencies as dispensaries, sanatoriums, better medical training and the specialized educational campaigns which must always be employed in a successful warfare against the disease.

ABSTRACT OF DISCUSSION

DR. L. L. LUMSDEN, Washington, D. C.: I am impressed with the position which I understand Dr. Palmer takes in regard to our most effective attack on the great problem of tuberculosis being through the application of general health activities. One of the large life insurance companies a few years ago made a careful statistical study of the incidence of certain diseases among its policy holders and found from the data that among persons under comparable conditions, economical, social, age and so on, those who had had typhoid fever were in the five-year period following the attack of typhoid fever much more likely to develop obvious tuberculosis than were those who had not had typhoid fever within the same period. It appears highly probable that in preventing other diseases such as typhoid fever, hookworm disease and malaria, which may be controlled by general sanitary measures, we are apt to make a definite impress on the tuberculosis rate. Economic conditions appear to influence, almost in mathematical ratio, the tuberculosis rate. Carefully compiled statistics in recent years showed that among government employees the tuberculosis rate was inversely proportionate, with remarkable regularity, to the salary scale. In the field of health activities it seems to me that more may be accomplished for immediate reduction of the tuberculosis rate through general hygienic measures and specific measures for the control of other infections than through measures directed specifically toward the control of tubercular infection itself.

DR. JUAN GUTERAS, Havana, Cuba: It would be worth while to take into consideration the development of the idea of contagion in the times preceding the discovery of the tubercle bacillus in the matter of contagion. The idea of contagion and the possible transmissibility of tuberculosis did not begin at the time of the discovery of the tubercle bacillus, and it is possible that the gradual elimination of this disease for years back began with the more or less popular idea that it is contagious, and it is worth while finding out whether this did not decrease the number of cases, or result in a diminution of the mortality in those countries in which the idea of contagion was more prevalent. I would suggest that a study be made of the statistics concerning tuberculosis in Italy, which was one of the countries in which the idea of the transmissibility of the disease, or its contagious nature, manifested itself early.

DR. JOHN P. DAVIN, New York: In connection with the theory concerning the scale of wages, the earnings and the decrease of tuberculosis as the result of a raise in wages: The better paid workman is on this account better able to provide for his needs, and the better able he is to do this the better he can live and the better citizen he should become. I have been greatly impressed by the members of the American Federation of Labor whom I have met. They are as a body a very high class of men, but the great trouble they have to overcome today is that an increasing price of the necessities of life invariably goes in excess of an increase in wages. Unless we can correct this disproportion so that an increased wage will produce or purchase something more than what it does today, we are just as badly off as we were before wages were raised. Under these circumstances I

think that in addition to studying the surroundings and improving the living conditions of the wage earner, and in attempting to eliminate tuberculosis by improving such earnings and such living conditions, we must study as well their sources of supplies; how much they have to pay for rent, how much they have to pay for food, and how much they have to pay for clothing and other necessities of life.

DR. W. C. WOODWARD, Boston: Apropos of the relation of wages to tuberculosis, we have to bear in mind that the men who receive the higher wages are presumably physically and intellectually the more capable men, and the question is not altogether whether the higher wage enables a man to avoid tuberculosis but also whether tuberculosis does not prevent him from earning the higher wage.

DR. A. T. McCORMACK, Bowling Green, Ky.: The problem presented here, that of tuberculosis, and the solution suggested by Dr. Palmer, is extremely gratifying to everybody interested in this subject. I think it is the history of all definite movements for the relief of a definite condition in public health matters that those interested approach it, first, as experts in the particular line, and then gradually spread out over more territory and begin to take in collateral problems until eventually every worker is interested in the general problem. In Panama we found out early that respiratory disease of the laborers was one of our greatest problems. A very interesting phase of the matter was the relative incidence of the respiratory disease, which was well known in the old Spanish towns, a section of the old residential part of the Canal where the houses had not been torn down until last year. They were occupied by very poor, squalid inhabitants, and were very bad quarters, a very large number of individuals being housed in one room as compared with the newer quarters built under the plans suggested by General Gorgas, and where really decent quarters were provided. These people all received the same wages. Yet, the respiratory diseases of old Spanish towns were 900 times as frequent as in the modern town. The individuals worked together on the locks and in the mechanical division, had the same kind of work and bought their food largely from the same commissary. In approaching this problem in Kentucky, where 23 per cent. of our rejections in the draft were on account of tuberculosis, we realized that it would be impossible to have enough sanatoriums to accommodate half of the cases of tuberculosis. We are attempting to approach the problem under the supervision of the county officers and with the general assistance in every county of the local medical organization, the establishment of regular hours in a tuberculosis dispensary and having a trained public health nurse follow up the cases, using the comparatively small number of beds in our sanatoriums as schools for the tubercular and attempting at the same time to broaden the education in such a way that all the individuals will be taught the ordinary lessons of how to prevent tuberculosis. I have been very much interested in the model Lincoln School in Lexington where they are opening free air schools on the top of the schoolhouse for children who are tuberculous, or for those who have shown symptoms of tuberculosis. It is rather poor policy that we are only taking care of those who have defects and permitting the well to lie in the same class rooms and school rooms with the affected ones, and not giving them the benefit of fresh air.

DR. GEORGE THOMAS PALMER, Springfield, Ill.: Dr. Lumsden and Dr. Woodward have pointed out a very important question in the handling of the tuberculosis problem. As physicians and health officers, I believe that we feel a little jealous at times of the invasion of our field by social agencies and yet when we consider the social aspects of the disease and particularly the relationship between wage and tuberculosis, we realize that we can never make big progress in the solution of the problem without a closer touch with charity organizations and with social agencies generally. As a matter of fact, I think that one of the most important steps in the solution of the tuberculosis problem is to bring about a closer appreciation on the part of physicians and health officers of the intricate social problems involved and on the other hand to develop a closer conception on the part

of social workers of the difficulties encountered in meeting the medical side of the problem. Tuberculosis is largely a social problem. In its solution we have to consider proper food supplies, proper housing, the comfort and happiness of the individual. Freedom from worry and care and anxiety necessitated a very much closer relationship than now exists between social agencies, public health officials and the medical profession. I was very glad, indeed, to have Dr. McCormack call attention to the lack of facilities for the care and protection of the well child. In our public health work and particularly in tuberculosis, we will not secure satisfactory results by making provision only for the physically deficient child and neglecting the individual in whom disease can be prevented. In dealing with tuberculosis, perhaps more than with any other disease, we realize that disease prevention is more important than disease suppression and that health promotion is an infinitely more important matter than either.

DR. W. C. WOODWARD, Boston: I hope that nothing I have said is going to connect tuberculosis with charity. A man who has tuberculosis or any other disease, and needs relief, ought to be able to get relief without being looked on as a mendicant or a pauper. As a citizen of the commonwealth or a person within the protection of the commonwealth, he is entitled to relief as a matter of moral right—or else our boasted civilization is a sham and a pretense.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

CHLORAZENE (See New and Nonofficial Remedies, 1919, p. 137).

The following dosage form has been accepted:

Chlorazene Surgical Gauze—Gauze impregnated with and containing approximately 5 per cent. chlorazene.

NOVASPIRIN.—Methylene-Citrylsalicylic Acid.—

A compound of anhydro-methylene-citric acid and salicylic acid.

Actions and Uses.—See New and Nonofficial Remedies, 1919, p. 250, under Acid Derivatives of Salicylic Acid (Acetylsalicylic Acid Type).

Dosage.—1 Gm. (15 grains) several times daily.

Manufactured by the Winthrop Chemical Company, New York City, U. S. patent No. 858,142 (June 25, 1907; expires 1924). U. S. trade mark No. 62,613.

Novaspirin is prepared by the action of methylene citric acid dichloride on salicylic acid.

Novaspirin is a grayish-white odorless, crystalline powder, pungent in the air, having a faint acridulous taste. It is almost insoluble in water; soluble in alcohol; less soluble in ether or chloroform. On heating Novaspirin with caustic alkalis, salicylate is formed, and on adding diluted acid to the alkaline solution, crystals of salicylic acid are separated. On long standing in presence of water or more quickly with alkalis, Novaspirin is split into its components. When heated in a dry test tube Novaspirin melts, and at higher temperatures formaldehyde and salicylic acid are liberated. The salicylic acid sublimes and is deposited on the cooler portions of the tube. Novaspirin when decomposed yields 62 per cent. of salicylic acid. After drying over sulphuric acid to constant weight, Novaspirin melts at 153.154° C. A saturated aqueous solution of Novaspirin (prepared without heat) does not produce a violet color with ferric chloride solution.

Incorporate 1 Gm. of Novaspirin; not more than 0.1 per cent. of ash remains.

Dry 1 Gm. of Novaspirin over sulphuric acid; not more than 5 per cent. of loss results.

NEW OBSERVATIONS ON LIPOIDS

The existence of a group of complex fats or fatlike compounds, long ago recognized in lecithin and more recently designated as phosphatids or phospholipins, has been the occasion for much speculation and even some semiscientific therapy in relation thereto. The facts that certain of these chemically obscure organic phosphorus compounds seem to be present in every living cell, that they abound in the nervous structures in large proportions, that they appear to play a part in fat metabolism and transport, that they are concerned in hemolysis and coagulation of the blood—such information has tended to fix attention on the word phosphatid and what it represents.¹ It is not surprising, therefore, that a widespread search has been made to locate and identify the phosphatids in different tissues and structures of both animal and vegetable origin.

The outcome of these investigations has been to make it seem more than probable that at least two well defined groups of these lipoids exist. In the type represented by the word lecithin, the earliest to be recognized as a chemical entity, the molecule is believed to represent a structure in which fatty acid radicals, glycerol, phosphoric acid and the nitrogenous base cholin are bound together in organic union. The hitherto isolated components of kephalin, a closely related lipid, are phosphoric acid, glycerol, aminoethyl alcohol, and stearic and linoleic acids. Under the name cuorin Erlandsen² described what he believed to be a third specific lipid; and the list of claims is by no means exhausted with this enumeration.

If one may judge from the history of medical biochemistry, etymological investigations are more easily conducted than chemical research. At any rate, the introduction of descriptive names has proved to be a ready means of disposing of a difficult problem in identification than is the structural analysis that leads to a positive result. The lipoids have heretofore been classed largely according to their solubility, with the result that many products of unlike composition have been obtained.

Largely through the labors of Levene and his co-workers it has been demonstrated that instead of a multiplicity of lipoids varying in composition with the variation of the organ which furnishes them many of the nondescript phosphatid products are in reality composed of a mixture, in varying proportions, of lecithin and kephalin, each having the structure required by theory. Levene and West³ have shown that the so-called lecithin of the egg yolk is a mixture of lecithin and kephalin. Levene and Komatsu⁴ have recorded a similar finding in the case of the lipoids of the heart muscle; and they⁵ have furnished evidence that so-called cuorin is presumably a mixture of kephalin and fragments of the latter. There is reason to believe that the supposedly characteristic phosphatids from other sources in the body will be similarly resolved into lecithin, kephalin and their derivatives or mixtures of them. If so, the results of such painstaking researches will dispose of the contention, essentially supported by continental biochemists,⁶ that individual organs of the same animal contain specific phosphatids and that the same organs of different species also contain distinct phosphatids. We are, rather, prepared to believe with Levene and Komatsu⁴ that the number of individual lipoids will be found to be rather limited, and that practically all animal organs contain the same lipoids.

ELIMINATION OF THE PHYSIOLOGIC PRODUCTS OF MUSCULAR WORK

Although the physiology of exercise has long interested scientific investigators, its importance has become greatly augmented of late through the demand for greater personal efficiency and a larger industrial output. Fatigue sets a limit to work. Greater working capacity can be attained only through an understanding of the nature of fatigue, so that it can be decreased as far as possible. For many years it has been understood that muscular activity is attended with the production of substances of an acid nature. When they accumulate in the contractile tissues, the efficiency of the muscle is soon impaired; and the satisfactory continuance of muscular performance depends on the removal or the destruction of the acid "fatigue products."

In view of this aspect of muscular activity, it is conceivable that hard work will result in the discharge of acid products into the circulation to an unusual degree. How are they disposed of? Are they oxidized, or neutralized, or excreted as such? It is now known that the blood maintains a constant reaction within very narrow limits, thanks to the remarkable devices

for the preservation of neutrality in the organism. Marked alterations in the acid or base forming properties of the diet do not essentially affect the reaction of the blood. Hastings¹ has noted that, although exercise may produce a diminution of the bound carbon dioxide of the blood plasma, the depletion does not progress to such a point, ordinarily at least, that the reaction of the plasma is significantly altered.

The real response to muscular activity is to be observed in the respiratory exchange and in the urine. The output of carbon dioxide through the lungs is an immediate outcome of work. The kidneys excrete the excess of acids of nonvolatile character. In his recent studies, Hastings¹ has found that the urine of men engaged in manual labor tended to be of a slightly higher acidity than that of men at rest. The urine of physically strong men was regularly slightly more acid after work than before. The urine of physically weak men showed wide variation in its reaction from day to day. When the muscular activity was such that the subject was intensely fatigued, there was invariably an increase in the hydrogen-ion concentration of the urine.

Talbert² has recently reported a similar change in the reaction of the perspiration during exercise. Hence the conclusion seems inevitable that vigorous muscular activity results in the production of acid products of such a kind or in such degree that they call on some mechanism other than the carbon dioxide excreting power of the lungs to eliminate them and preserve the physiologic reaction of the tissues intact.

THE PROBLEM OF PROTEIN

Ever since the war threatened the integrity of the world's food supplies, the advocates of physiologic economy in nutrition have found a more sympathetic hearing than in the older days of peace and plenty. Some of the most energetic opponents of the "low protein" diet, at one time advocated by Chittenden, have almost completely reversed their judgment on this subject. They had seemingly found their fears dissipated by the experience of thousands of persons who were compelled by the dire necessities of food shortage to live on scant rations, particularly so far as the foods richest in protein were concerned. The reports from Germany and the central empires regarding the effect of the stringent regimen on the health and morale of the people had an encouraging ring in the early years of the great conflict. Furthermore, the extensive experiments on undernutrition which Benedict and his collaborators conducted on volunteers from the International Y. M. C. A. College at Springfield, Mass., have been interpreted to indicate a surprising adjustment of the depleted human individual to a lower level of metabolism.

Some of these contentions have already been commented on in *THE JOURNAL*. English physiologists have inclined, during the war, to accept Bayliss' dictum: "Look after the calories and the proteins will look after themselves." Nevertheless, the Food (War) Committee of the Royal Society of London has been cautious in its published conclusions. As a rule, the British report notes, one may say that the protein in the diet of the "average man" should not fall below 70 or 80 gm. (from 2½ to 3 ounces) a day. The protein should be derived from a mixed diet and should include, if possible, a certain amount of protein of animal origin.¹

The basis for many of the deductions regarding the effect of parsimony in diet has been derived from metabolism experiments on man or from statistical and other reports regarding the "general health" of large groups of persons. More recently, a novel prominence has been given to experiments concerning nutrition conducted on the smaller animals. Some of these, like the rat, have a comparatively short span of life, so that the various phases of growth and adult existence can be observed within a period of months rather than years. Through the aid of this modern mode of physiologic dietary analysis, the adequacy or debilitating effect, respectively, of various regimens can be observed at different periods in the life cycle. When months correspond with years of human existence, the basis for observations is somewhat safer than that furnished by a few days' or weeks' records of man. McCollum and his collaborators² who have had large experience in this domain insist that the results of experiments with grown men restricted to experimental diets for a few weeks or months do not form a safe basis for drawing conclusions as to the quality of the foods employed. Certain deductions may be warranted from general observations on children living on faulty diets, and important deductions may safely be drawn from the experiences of large groups of people living on more or less restricted lists of food-stuffs. Beyond this, it is maintained, we must be guided in human nutrition by the results of animal experimentation, in which the conditions can be made sufficiently rigid to bring into stronger contrast the faults of certain types of diets as contrasted with others.

If the validity of this standpoint, which so many interesting recent researches have tended to substantiate, is admitted, we may be prepared for McCollum's conclusion regarding the debated protein factor. He says:

All our experience with diets of low protein content have indicated that animals do not remain in a state of optimum

well being even when the content of protein is sufficiently high to maintain in certain individuals the initial body weight over as much as 10 per cent. of the normal span of life. We believe that health and vigor are promoted by a liberal intake of protein of good quality better than by any diet in which there is a tendency toward parsimony with respect to this dietary factor. It should not be lost sight of, however, that there are other factors in nutrition which are of equal importance with protein, and that if the optimum well being is to be attained the diet must be rightly constituted with respect to all its parts. In addition to this the prompt elimination of the fecal residues is essential and is a great relief to the tissues of the entire body.²

This is a sane hypothesis for the dietary program of the reconstruction period on which the civilized world is now entering.

RELATION OF SPINAL PUNCTURE TO THE PRODUCTION OF MENINGITIS

It has become an accepted practice to make lumbar puncture in suspected cases of meningitis. Meningeal symptoms often occur in acute infectious diseases, and it is not uncommon to make diagnostic puncture in such cases. In general it has seemed advisable that spinal puncture should be made at the earliest possible moment, without any hesitancy, even when there may be some reason for doubt as to the presence of meningitis. There are many reasons assigned for such action: Thus, it is generally assumed that spinal puncture can do no harm, and that examination of the spinal fluid offers a ready and trustworthy means of diagnosis, while symptoms cannot always be relied on. Furthermore, experience has demonstrated that meningitis treated early promises a better outcome than when treated late. Consequently it is not uncommon to inject serum intraspinally at the same time the diagnostic puncture is made. Spinal puncture is often made, of course, in what seem unmistakable cases of meningitis, and yet the spinal fluid may prove to be normal, but in such cases actual meningitis sometimes develops after the puncture. The question has therefore been raised by Weed, Wegeforth, Ayer and Felton³ whether the withdrawal of cerebro-spinal fluid during a septicaemia is a factor in the production of meningitis. These observers found that in animals the removal of cerebro-spinal fluid during an artificial septicaemia may be followed by a localization of the infection in the meninges. According to a recent report by Wegeforth and Latham,⁴ fifty-five of ninety-three cases, in which meningitis was suspected, and in which lumbar puncture was done, yielded a clear fluid; among these patients, however, were six who at the time of puncture gave positive blood cultures, five of whom subsequently developed meningitis.

The close analogy between the clinical and experimental observations cited indicates that there may be dangers in lumbar puncture which should restrain

physicians from routine punctures in acute infections. Wegeforth and Latham recommend that careful blood cultures be made before the puncture, and "that in acute diseases, in the absence of definite signs of irritation of the central nervous system, lumbar puncture should be avoided unless it is first shown that the blood is free from infection." In cases of meningococcus sepsis, they are of the opinion that the logical procedure is to treat the blood infection by intravenous administration of serum, and to avoid spinal puncture until signs of involvement of the meninges are present. Under ordinary circumstances, however, the recognition of meningococcus sepsis is rather difficult, and since delay is dangerous the rational procedure would be to combine the intravenous and intraspinal treatment. The objection to the intraspinal introduction of serum in cases in which the spinal fluid is not pathologic is based on the observations of Flexner and Amoss⁵ on poliomyelitis, and of Austrian⁶ on meningococcus sepsis, to the effect that the introduction of serum favors the localization of the blood infection in the meninges; but then again this has been recently disputed by Amoss and Ebersson.⁷

The precautions recommended by Wegeforth and Latham are of importance in acute general infections. Nevertheless, until we have better means of differentiating between the various forms of meningitis, it would not appear advisable to delay spinal puncture unduly.

Current Comment

SOME LESSONS FROM THE EXPERIENCES WITH COMMUNICABLE DISEASES IN THE ARMY

We must all appreciate that the experience of our medical officers and epidemiologists in the world war will be productive of educational benefit when the observations have been correlated and interpreted. Diseases once the terror of armies have been conquered by scientific medicine, but new maladies have replaced them and presented new problems for solution. During the Spanish-American War, typhoid was an ever-present source of worry, but was almost completely eliminated in the recent warfare. On the other hand, it is well known that during 1918 civilian communities suffered greatly from the influenza and pneumonia invasion, but that the death rate was higher among the soldiers in camp than among the civilians. One out of every four men had influenza; one out of every twenty-four men encamped in this country had pneumonia; one out of every sixty-seven died.⁸ Vaughan and Palmer remind us⁹ that, compared with epidemics for

which we have fairly accurate statistics, the death rate at Camp Sherman in the fall of 1918 is surpassed only by that of plague in London in 1665 and that of Philadelphia in 1793. The plague killed 14 per cent. of London's population within seven months. Among the lessons that already are emerging from the details of the army medical experience of last year, the factor of the natural susceptibility of individual persons takes a conspicuous place. The army experts have ascertained that disease was in general more prevalent in the army in this country than among our soldiers abroad. The exceptions to this were dysentery, meningitis and scarlet fever. Vaughan and Palmer conclude that "there is more disease in this country because the men are more susceptible. The home army is more susceptible because it contains a greater proportion of new men. The new, unseasoned recruit is therefore responsible for more sickness than is caused among seasoned men by undergoing the hardships of physical and mental fatigue and exposure of combat." A further highly important lesson concerns the importance of prosecuting more vigorously than ever before the effort to learn the etiology of the respiratory diseases that have proved so unexpectedly menacing. Smallpox, typhoid, tetanus and diphtheria have yielded to the investigator's persistence. We may confidently expect a comparable success against the ravages of influenza, pneumonias, scarlet fever and measles when once their true causation has been adequately elucidated.

THE THERMAL DEATH POINT OF TRICHINA LARVAE

Parasitic organisms are not uncommon as constituents of certain animal tissues: trichinae, the larvae of *Trichina spiralis*, occur not rarely in pork, and calves and sheep may also be infected. The meat is not rendered unfit for human consumption on this account, for any procedure that will destroy the life of the parasite without rendering the flesh unfit for dietary use permits conservation of food products. The cooking of trichinized meats has long been looked on as accomplishing this result. In view of the fact that enormous quantities of pork products are handled every year in this country on a factory scale under conditions to which household methods of cooking do not apply, it has become desirable to know with considerable accuracy what the limits of viability of trichinae in flesh are. According to a recent investigation at the Bureau of Animal Industry,¹ the vitality of the larvae of *Trichina spiralis* is quickly destroyed by exposure of the parasites to a temperature of 55 C. (131 F.), gradually attained, the result apparently of irreversible coagulation changes in the protoplasm. This temperature may be considered the thermal death point. The experiments further indicate that when exposed to temperatures in the neighborhood of 50 C. (122 F.), trichina larvae die if the application of heat is sufficiently long continued, apparently as a result of

exhaustion following excessive activity to which they are stimulated by the heat. From a practical standpoint, the continuous heating at temperatures below the lethal point has very little importance. From the standpoint of public hygiene, however, it is important to know that the rules enforced in connection with the federal inspection of meat products include a certain margin of safety. The Bureau of Animal Industry has selected a temperature of 137 F. (58.33 C.) as the minimum temperature to which pork and products containing pork are required to be heated when cooked in establishments operating under its jurisdiction. Smaller establishments free from such careful inspection are frequently derelict with respect to the necessity of heating uninspected pork products. Sausages are particularly liable to careless treatment when they are prepared in small, irresponsible establishments. Not a few of the cases of trichinosis still encountered in clinical experience may be traced to such negligence.

THE CALDER BILL—A VICIOUS MEASURE

Senator Calder of New York has recently introduced a bill that would make practically all products that now come under the purview of the federal Food and Drugs Act immune from state laws. The bill provides, in effect, that no state or city law relating to the adulteration or misbranding of foods, drugs or medicines, "or regulating the branding thereof," shall apply to, or interfere with, the sale of any foods, drugs or medicines in package form which have been transported in interstate commerce and are not adulterated or misbranded under the provisions of the federal law. The effects of such a bill, should it become a law, would be utterly vicious. It would mean that when a state has a law that offers greater protection to the public than the federal law offers, the state law would be rendered inoperative. For instance, the severe setback, which the glucose interests received at the hands of the state of Kansas a few months ago, could never have happened if the Calder bill had been a law. Our readers will remember that Kansas requires the manufacturers of syrup-mixtures to declare definitely on the label the percentages of each ingredient. The Corn Products Refining Company sold a syrup-mixture which was found to contain 85 per cent. glucose, 10 per cent. molasses and 5 per cent. sorghum. The company did not declare the proportions of the ingredients on the label; the Kansas authorities, under the state law, successfully proved the right of the state of Kansas to enact and enforce the ingredient-percentage requirement of its law. Another instance of what the Calder bill would do if it became a law can be understood by recalling the case of Nebraska against "Hall's Catarrh Cure." This nostrum, put out by a power in the "patent medicine" world, was still labeled a "cure" years after the federal authorities had forced less influential concerns to remove the word "cure" from their labels. Nebraska, under its own food and drugs law, prosecuted the Hall concern and won. As a result, it is now "Hall's Catarrh Medicine." Louisiana, as

1. Ransom, B. H., and Swartz, B.: Effects of Heat on Trichinae, J. Agric. Res. 17: 201 (Aug. 15) 1919.

THE JOURNAL recently pointed out, has a law prohibiting the sale of venereal disease remedies except on the written prescription of a licensed physician. This has stopped the sale in that state of the vicious and dirty nostrums sold for the self-treatment of syphilis and gonorrhea. Should the Calder bill become a law, a manufacturer of a disgusting and dangerous "patent medicine" of this type (provided he lives outside of the state of Louisiana) could sell his stuff in Louisiana and, figuratively speaking, put his thumb to his nose at the state authorities. While Mr. Calder's motives in introducing this bill are doubtless of the best, THE JOURNAL is convinced that the effects of the bill, should it become a law, would be altogether bad. Such a law would, in effect, enable unscrupulous manufacturers of food products and medicines to enjoin the various states of the Union from passing any laws, or enforcing any laws already passed, that are stricter than the federal law. Powerful interests might find it easier—and less expensive—to control legislation in Washington than in forty-eight individual states.

SECRET REMEDIES AND THE PRINCIPLES OF ETHICS

Many hundreds, possibly thousands, of inquiries are received each year by THE JOURNAL from physicians asking for information on, or an opinion of, certain proprietary remedies. In many instances the preparations in question are essentially secret in composition, although advertised to the profession under a fair-seeming exterior of apparent frankness. There are on the market today—and used by members of the American Medical Association—dozens, yes scores, of widely advertised proprietaries that are, to all intents and purposes, secret. The physicians who prescribe them do not know and cannot know what they are giving their patients. On this point Section 6 of Chapter II of the Principles of Medical Ethics of the American Medical Association says:

"... it is ... unethical to prescribe or dispense secret medicines or other secret remedial agents, or manufacture or promote their use in any way."

The inherent and basic reasonableness of the various requirements of the Principles of Medical Ethics needs no exposition or defense. A large number of proprietary remedies which at present degrade medicine would be wiped out of existence or, at any rate, go over to the "patent medicine" class, where they belong, if physicians would live up to Section 6, Chapter II, of the Principles.

Vivisection in England During 1918. The Home Office return for last year shows that the total number of vivisection experiments amounted to 77,601, being 22,000 more than in 1917. . . . Twenty-nine thousand investigations were undertaken on behalf of government departments and public health authorities, and 37,000 for the preparation, standardizing and testing of serums, vaccines and drugs. Cancer research work involved 6,027 experiments; of these, all but 137 were carried out without requiring the use of an anesthetic under the act. In England and Scotland twenty three new places, mostly laboratories connected with military hospitals or municipal establishments, were registered for the performance of experiments during the year. The total number of licenses granted was 701. *The Medical Press.*

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Sanatorium Opened.—Pine Lodge Sanatorium, located a little west of Colfax, was opened and dedicated early in August. The building is a two story structure finished in gray stucco. It will accommodate nineteen patients, and is under the charge of Dr. Robert A. Peers, Colfax.

CONNECTICUT

Personal.—Dr. Daniel Cantarow, Hartford, sailed for England, September 12.

Reunion at Gaylord Farm.—Gaylord Farm Sanatorium, Wallingford, the first county tuberculosis sanatorium in America, and one of the oldest in the country, held a homecoming reunion, September 13, at which about 300 of the 1,200 graduates were present.

Tuberculosis Association Receives Allotment.—The National Tuberculosis Association has sent to the Connecticut State Tuberculosis Commission a check for \$13,690.16, the final allotment from the fund guaranteed by the American Red Cross to the National Tuberculosis Association for giving up the sale of Christmas seals. This brings the total amount received by the state commission to \$43,710.02.

State Fight on Tuberculosis.—The Connecticut State Tuberculosis Commission announces that it is putting into effect a plan to fight tuberculosis in its incipency, utilizing the information obtained from army records of the rejection of many men from the service because they were suffering from early forms of the disease. Tuberculosis organizations in every city and large town in the state will take cognizance of the list of rejects and endeavor to place them under treatment. It is believed that 60 per cent. of the incipient cases will respond to treatment and that a large proportion will be restored to normal activities by the recommended courses of exercise, rest and appropriate nourishment. Of the total number of drafted men from the state, 1,024 were rejected on account of tuberculosis. Of these, 127 were from New Haven, 121 from Bridgeport, 112 from Hartford and 106 from Waterbury.

GEORGIA

Examining Board Reappointed.—The governor, August 29, announced the reappointment of the following members of the state board of medical examiners: Drs. Alfred F. White, Florilla, Henry W. Terrell, LaGrange, and Harold F. McDuffie, Atlanta.

Personal.—George A. Traylor, Lieut.-Col., M. C., U. S. Army, Augusta, has returned and has resumed practice after an absence of two years in military service.—Dr. Will L. Wood, Atlanta, has been elected health commissioner of Fulton County.—Dr. Claude A. Smith has resigned as city bacteriologist of Atlanta, and has been succeeded by J. E. Acker, assistant city chemist and bacteriologist.—Dr. Walter E. Barber, Atlanta, has been reappointed a member of the health board of Fulton County.

ILLINOIS

Hospital Founder Dies. Mr. F. M. Elliott, founder, and for twenty years president of the Evanston Hospital, died suddenly at his home in Evanston, September 16.

Sanatorium for Kane County. The board of supervisors of Kane County, at a meeting held in Geneva, September 19, appropriated \$100,000 for a county tuberculosis sanatorium.

New Sanatorium. The new tuberculosis sanatorium for McLean County, Fairview, located just north of Normal, is now in full running order; almost all of the beds are occupied, and many patients are already showing improvement and increase in weight.

Presentation to Base Hospital Commander.—The enlisted men of Base Hospital No. 12 recently sent their commanding

officer a hand hammered sterling silver platter engraved with the following inscription: "Presented to Major Payson L. Nusbaum, Chicago, commanding officer at Base Hospital No. 12, by the enlisted men of that organization on completion of twenty-two months of active service in France as a token of their esteem and regard."

Illegal Practitioners Fined.—H. C. Crabtree of Freeport and Samuel Leonard of Shannon, Carroll County, were arrested by the Illinois Department of Registration and Education for practicing medicine without a license and were fined, respectively, \$50 and \$100 and costs. The public school nurses of Carroll County aided the department in securing the necessary evidence against Leonard.—Mrs. Anna Zeolkowski, Chicago, is said to have been fined \$25, September 16, for practicing medicine without a license.—J. G. Biemas, Chicago, September 16, is said to have pleaded guilty to having set a broken leg, and to have been fined \$5.

Personal.—George G. Davis, Lieut.-Col., M. C., U. S. Army, Chicago, has recently been discharged from military service and has returned home.—John A. Hornsby has returned to Chicago.—Dr. Harry E. Mock, Chicago, has again been commissioned colonel, M. C., U. S. Army, and appointed delegate to the International Conference to be held in Rome, next month.—Clarence L. Wheaton, Major, M. C., U. S. Army, Chicago, was honorably discharged from military service at Camp Grant, September 19, after twenty-two months of continuous service at the camp in charge of the tuberculosis work.

CHICAGO

Attend Chemical Exposition.—About 15,000 visitors are attending the Fifth National Chemical Exposition. Meeting in conjunction with the exposition are a number of technical societies. Dyes, pharmaceuticals and machinery constitute the major portion of the exhibit, but other phases are adequately represented, such as the resources of America and Canada, the public safety work of the Bureau of Mines and accomplishments of the Chemical Warfare Service.

IOWA

New Sanatorium.—St. John's Hospital Farm, near River-ton, is to be a tuberculosis sanatorium auxiliary to St. Joseph's Hospital, Springfield. The farm contains 500 acres and buildings are to be erected from time to time as necessary. A sanatorium building is practically complete, and buildings are to be erected for a hospital for crippled children, and one for nervous diseases.

Personal.—David S. Fairchild, Jr., Col., M. C., U. S. Army, Clinton, formerly chief surgeon of the Forty-Second (Rain-bow) Division, and now on duty at the Surgeon-General's Office on war combat medical histories, has been cited and has received a personal letter from General Pershing commending his work and expressing his appreciation of the valuable services rendered to the American Expeditionary Forces as division surgeon.—Dr. R. H. Sylvester, clinical psychologist at the Iowa State University, Iowa City, has been selected as chief of the health center at Des Moines, with headquarters in the court house.—Dr. Walter L. Biering, Des Moines, returned home, August 29, after two months spent in Europe in the interests of the National Board of Medical Examiners.

KANSAS

Personal.—Dr. J. McLean Moulder has been selected as head of the Methodist Hospital, Kansas City, for another term.—Dr. J. Carroll Montgomery, Manhattan, has been placed in charge of the work of the United States Public Health Service in Cherokee County with headquarters at Columbus.

MARYLAND

Meetings.—The Maryland Psychiatric Society and the Baltimore County Medical Association held a joint meeting on September 17, at Middle River, as the guests of Dr. J. W. Harrison. Following a luncheon, addresses were delivered by Capt. Hubert C. Knapp and Dr. Richard F. Gundry of Catonsville.

Typhoid is Epidemic.—At Hagerstown, typhoid fever has reached an epidemic stage. The total number of cases reported so far is thirty, and the Red Cross is preparing to bring nurses to the city from other cities if the situation does not improve. The county health board is in consultation

with the state board of health regarding the situation. So far all cases are traceable to milk furnished by one dairy-man, who had used infected water from two wells and a spring on his farm. All milk, as well as the city water and wells and springs, in the community, will be tested for typhoid bacillus. Antityphoid inoculation is being used to check the disease.

Aid for the Backward.—Provision for the care and training of boys and girls unable to advance in the public schools will be considered at a conference called at the request of Dr. Francis Lee Dunham of the Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital. One of the suggestions offered is that some arrangement be made by which these children may spend part of their time in school and part in industrial training. Mr. Fox of the state board of labor and statistics has pointed out that since October 1, last, when the new law dealing with delinquent children became operative, the state board has handled cases involving 260 retarded boys. Twenty-six of the boys were hard to handle and fully 75 per cent. of the total number had juvenile court records. It has also been suggested that the school survey commission devote special attention to the training of backward and mentally deficient boys and girls and include in its recommendation some system of training them. Under the law, children between the ages of 14 and 16 years are not permitted to work, and cannot be forced to attend school. The result is that many of them drift into the juvenile court or are sent to institutions. All this can be overcome through the cooperation of proper officials and others interested in the development of children.

Personal.—Ernest D. Everett, Capt., M. C., U. S. Army, Lakeview, Ore., who has been on duty as ophthalmologist and otorhinolaryngologist at U. S. General Hospital No. 21, Carlisle, Pa., since his return from France in June has been separated from the service and located at Frostwood.—John F. Keenan, Brentwood, has been appointed medical referee of the Pension Bureau, Washington, D. C., succeeding Dr. Thomas Featherstonhaugh, resigned.—Capt. E. P. Dameron, Medical Corps, has been transferred from U. S. Army General Hospital No. 2, Fort McHenry, to Jefferson Barracks, St. Louis, where he will be assistant to former Lieut.-Col. Blair, who had supervision of the maxillo-facial cases of the entire army until recently. Captain Dameron came to Fort McHenry from U. S. Army General Hospital No. 11, Cape May, N. J.—Col. Thomas J. Leary, U. S. Army, has arrived at U. S. Army General Hospital No. 2, Fort McHenry, to succeed Lieut.-Col. Julius H. McHenry. Colonel Leary recently returned from France, where he was in command of Evacuation Hospital No. 5. With him come five medical assistants of the regular army to assist Major Gavin Hamilton in the surgical work.—Dr. William S. Thayer, professor of medicine in the Johns Hopkins University, has returned to Baltimore after two months spent in France in recuperating from the strain he was under during the war. Dr. Thayer was chief medical consultant of the American Expeditionary Forces.—Dr. H. W. Wheaton, who recently returned from service overseas, has accepted a position in the neurologic department of the Sheppard and Enoch Pratt Hospital, Towson.—Dr. Frank E. Shipley, Savage, has been appointed resident physician at the Maryland House of Correction by the state board of prison control and Dr. Corbin Street, Baltimore, has been appointed visiting physician.

MICHIGAN

Typhoid Fever in Detroit. During July, there were twenty-nine cases of typhoid fever in Detroit and these were probably directly due to contact with lake and river waters in the vicinity of the city, where pollution by sewage is said to exist without interruption.

Tuberculosis Clinic Opens.—A free clinic, under the direction of the Michigan Anti-Tuberculosis Association, was opened at the Spies Library, Monmouth, September 19, and will continue for three days under the direction of Dr. Edwin R. VanderSice, Ann Arbor, and Dr. William R. Vis, Grand Rapids.

Personal.—Victor H. DeSomoskroy, Capt., M. C., U. S. Army, Flint, has been offered the rank of Lieutenant-Colonel in the Polish Army and has gone to Poland as a member of the American Commission for the relief of the typhus situation in that country.—Dr. Leon B. Harris has been appointed city physician of Saginaw, succeeding Dr. Fred W. Edmann.—The Houghton County Medical Society gave a banquet, September 1, in honor of Dr. Joseph

E. Scallan, Hancock, who is entering on his forty-fifth year of medical practice in the copper country.

MINNESOTA

Personal.—Dr. I. Pemberton P. Hollingsworth, St. Paul, has been appointed assistant health officer for Sioux Falls, S. D. —Dr. G. B. Ker Granger, Rochester, has resigned as assistant city health officer of Rochester and will be succeeded by Dr. Walter F. Bleifuss, Elgin.

Clinic Organized.—The Pipestone Clinic has been organized by Drs. William J. Taylor, Eugene G. McKewen and W. E. Roberts, on the second floor of the Pipestone National Bank Building. The temporary hospital located at 84th Kenwood Street will be ready to receive patients, October 1.

Conviction Confirmed.—The Minnesota Supreme Court is said to have confirmed the conviction of Dr. Clarence D. Whipple, Minneapolis, on the charge of selling habit-forming drugs to a drug addict in violation of the law. Dr. Whipple claimed a thirty-day stay of sentence, August 23, and was released on bail of \$2,500.

Health Association Work.—The St. Louis County Health Association has sent out an appeal to all health officers and others engaged in health work calling for their cooperation. There is at present about \$4,000 available for expenditure and it is proposed that this shall be devoted to antituberculous educational work in the county. —The annual meeting of the Glaucoma County Public Health Association was held in Redwood, September 8, to elect officers, receive reports of work, and to determine the program and budget for the coming year.

MISSOURI

Typhoid in Lafayette County.—Typhoid fever is reported to be epidemic in the southeastern part of the county where more than twenty cases with three deaths have occurred. Samples of milk and water have been sent to the state university for analysis. Several cases have already developed around Houstonia and Concordia.

Treatment of Narcotic Addicts.—The Kansas City Board of Health has established a system of licensing reputable physicians to treat narcotic addicts and is placing restrictions on all physicians in prescribing and administering narcotics. All addicts are required to register with the board and will be assigned for treatment to the physicians especially licensed to do this work.

Neurologic Department for Hospital.—The Springfield Hospital at Springfield has purchased and is operating as a neurologic department the hospital established by the late Dr. Samuel A. Johnson for the treatment of mental and nervous diseases. The board of managers has also purchased additional property costing several thousand dollars which will be converted into a home for the nurses. Another improvement is the establishment of a modern laboratory which will be under the direction of Dr. Murray C. Stone, Springfield.

Clinical Section of Society Organized. Members of the St. Louis Medical Society have formed a clinical section of that body for the purpose of organizing and systematizing the clinical material in St. Louis so that visiting physicians may have the opportunity to benefit by attendance. A daily bulletin will be issued to these physicians who register with the secretary of the clinics, giving the location of the hospitals where clinics will be held and the character of the work to be done. For the present no charge will be made for registration.

Personal.—Dr. Ott S. Wilcox, formerly of Welch City, has been appointed the position of examining medical officer for the Board of Vocational Education for District No. 9, Lincoln, Nebraska at St. Louis. He has accepted a commission in the United States Public Health Service under which special work in vocational education is being directed. —Dr. J. C. Allen, St. Louis, who served in the Medical Corps of the Army during the great war and was recently honorably discharged with the rank of colonel, has again entered the service of the Army with the rank of colonel and has been assigned to Rome as American representative at the International Congress of Surgery, which will be held in Rome, October 1. —Dr. and Mrs. Allison sailed for Rome, September 17, to accompany government transports. —Dr. William L. H. Smith, Kansas City, has been attached to the General Hospital, American Expeditionary Force. —Dr. Morris S. McGuire, Arras, died of a heart accident, August 8, which confined him in the French hospital for a month, and necessitated the amputation of all the toes on his right foot.

NEBRASKA

Personal.—Dr. James F. Edwards, Pittsburgh, who was chief surgeon at Camp Mills, N. Y., until his discharge from the government service, September 1, has taken over his new duties as health commissioner of Omaha, succeeding Dr. Ernest T. Manning, resigned. —Dr. Samuel J. Stewart, Hastings, has been appointed superintendent of the State Institution for the Feeble-minded, Beatrice, and will assume his new duties, November 1.

NEW YORK

New York City

Personal.—Dr. Sidney R. Burnap has been appointed associate dean of the College of Physicians and Surgeons of Columbia University. This is the first time the university has had an associate dean.

Well-Known Chemist Decorated.—Dr. L. H. Baekeland, New York, honorary professor of chemical engineering in Columbia University, has been decorated by King Albert, with the Order of the Crown of Belgium.

Conference on Prevention of Influenza.—A conference was held in this city during the past week which marks the beginning of a federal, state and municipal effort to prevent the threatened recurrence of influenza. Dr. William H. Park, director of the laboratories of the department of health; Dr. George W. McCoy, director of the laboratories, U. S. P. H. S.; Dr. M. J. Rosenan, professor of hygiene and preventive medicine in Harvard University, and Dr. E. O. Jordan, professor of bacteriology in the University of Chicago, were present at the conference and agreed to unite their efforts in forestalling an epidemic. Following the conference Dr. Copeland announced that circulars of warning and instruction will be distributed through the schools. He also urges physicians to report every case of influenza and announces that the department of health is prepared to give a vaccine to physicians and to administer it at the board of health clinics.

Scholarships Open to Negroes.—According to an announcement made by the General Education Board of the Rockefeller Foundation, through its secretary, Abraham Flexner, Julius Rosenwald of Chicago has offered six scholarships of \$1,200 each to pay the expenses of especially qualified negro students doing postgraduate work in such fundamental medical sciences as pathology, bacteriology, physiology, pharmacology, physico-chemistry, etc. The committee in charge of the awards will consist of Dr. William H. Welch, Baltimore, Dr. David L. Edsall, Boston, Dr. Victor C. Vaughan, Ann Arbor, Mich., and Abraham Flexner. Appointments will be made in 1920, toward the close of the year's session, to be effective for the succeeding academic year. Applications may be made to the secretary of the General Education Board by individuals or by institutions in behalf of individuals, and should contain a full account of the education—general and professional—of the applicant, including a transcript of his entire record in the medical school.

OHIO

Health Department Moves.—The state board of health moved, September 9, from the Ohio State University to the Clinton Building, Columbus.

New Officers.—The Tenth District Medical Society at its annual meeting held in Marysville, September 5, elected Dr. James E. Hines, Columbus, president; Sylvester Goodwin, Circleville, secretary, and the presidents of the various county medical societies, vice presidents. The next meeting will be held in Chillicothe.

Appointment Rejected.—The board of directors of the University of Cincinnati, September 9, is said to have rejected the appointments of the faculty of the industrial medicine and public health department made by Dr. Carey P. McCord. This department is not directly associated with the University of Cincinnati, although the board of directors is authorized to make appointments. The financing of the department is by subscription of business men of Cincinnati.

Second Councillor District Medical Society Holds Medical Chautauqua.—A "Medical Chautauqua" was held by the Second Councillor District Medical Society, September 22 to 26, at Dayton. The meetings are designed to furnish physicians an opportunity to obtain postgraduate lectures and clinics at a minimum expenditure, each physician paying a fee of ten dollars to defray the expenses of the lectures.

Among those delivering clinics and lectures during the present session were Drs. Richard C. Cabot, Boston, Harold N. Cole, Boston, A. E. Sterne, Indianapolis, H. Brooker Mills, Philadelphia, W. D. Porter, Cincinnati, M. H. Fischer, Cincinnati and G. W. Crile, Cleveland.

Agree on Sale of Sanatorium.—The county commissioners of Summit, Portage, Columbiana, Trumbull and Stark counties, at a meeting held at the Springfield Lake Tuberculosis Hospital, September 12, agreed to a proposition made by Summit County for the purchase at cost of the interests of the four counties owning the hospital. By this agreement Summit County will pay each of the other counties the amount of money invested in land and property. The original cost of the institution was \$298,000 with about \$25,000 additional taken from the maintenance fund for equipment and alterations. The share of Stark County is said to be \$80,011.21. Stark County proposes to unite in a single group the county workhouse, county infirmary and county tuberculosis sanatorium, financing the plan by the sale of the present infirmary site of 311 acres which is estimated to be worth \$1,000,000.

Personal.—Major Guthrie McConnell has accepted a position as director of the research institute of the National Dental Association, Cleveland.—Dr. J. Edward Pirrung, Cincinnati, has been elected surgeon-general of the National Army and Navy Union.—Dr. John H. Berry, Lima, has been appointed superintendent of the Athens State Hospital, succeeding Dr. Ora O. Fordyce, Athens, who was recently transferred to the Toledo State Hospital.—Dr. Valloyd Adair has succeeded Dr. Charles R. Meek as health officer of Lorain.—L. H. Van Buskirk, for six years in the engineering department of the state board of health and for the last four years director of the division of laboratories, has resigned to join the teaching force of the Medical College of the State University of Ohio, Columbus.

PENNSYLVANIA

District Meeting.—The thirteenth annual meeting of the Fifth Consorial District, consisting of Adams, Cumberland, Franklin, Fulton and York counties, was held at the Colonial Hotel, York, July 24, and the following officers were elected: president, Dr. Theodore H. Weakly, Franklin County; vice presidents, Drs. John C. Feltz, Adams County; Samuel E. Mowery, Cumberland County; and Joseph C. Atkins, York County; and secretary, Dr. James P. Dalley, Adams County.

Philadelphia

First Aid Course.—Public school pupils will learn emergency first aid as part of their regular class room study when the junior American Red Cross begins its first aid course in the schools, October 1. The course will include, beside first aid, accident prevention and home hygiene.

Personal.—Dr. John H. Gibbon will sail for France, October 8, to represent the United States government in the interallied surgical conference to be held in Paris.—Dr. J. Torrance Rugh, professor of orthopedic surgery, delivered the introductory address at the ninety-fifth annual session of the Jefferson Medical College of Philadelphia in the clinical amphitheater of the Jefferson Hospital, September 22.

VIRGINIA

Sanatorium in Danville.—A campaign is under way this month in Danville to raise \$90,000 for the erection of a new tuberculosis sanatorium, the buildings for which will be erected on the tract of land donated to the city by Mr. R. L. Dihrell.

Professional Building.—A twelve story building is to be erected at Freemason and Duke streets, Norfolk, to be known as the Medical Building, and to be occupied by physicians and dentists. The building and site will represent an outlay of approximately \$400,000. The first floor of the structure will be given over to stores, and the twelfth floor will be arranged for assembly and conference rooms for the local medical organizations, the rest of the building being used for offices.

Personal.—Dr. Charles V. Carrington, Richmond, is reported to be seriously ill in St. Elizabeth's Hospital.—Dr. George W. Schenck, Norfolk, has returned from France, and has resumed his duties in the Woman's Hospital, New York City.—Dr. Edgar C. Harper, whole-time health officer for Prince William County, is in charge of the county health campaign for which funds were raised last spring. The campaign will last one year, and will include school inspec-

tion, examination of schoolchildren, and a sanitary survey of the county.

Hospitals Chartered. The Providence Hospital Association has been incorporated at Danville with the object of establishing and maintaining a benevolent and charitable hospital. Messrs. G. W. Goode and J. Alexander Valentine, and Drs. Albert L. Winslow, Frederick W. James and Abel E. West, all of Danville, are the incorporators.—An amendment to the charter of the Johnston-Willis Sanatorium, Richmond, to increase the capital stock from \$100,000 to \$250,000 has been approved. The increase is to allow for the erection of a modern hospital building at Kensington Street and the Boulevard. Dr. A. Murat Willis is the president, and Dr. J. McCaw Tompkins, secretary, of the institution.

WISCONSIN

Dinner to Service Men.—The Milwaukee County Medical Society gave a dinner in honor of its 120 members who were in the military service and have returned thereon, September 11, at the Milwaukee Athletic Club. Dr. Gustav J. Kaunheimer was toastmaster, Dr. H. Manchester Brown gave the address of welcome and Col. Gilbert E. Seaman responded for the service men.

Clinic Course at State University.—During the last year 247 physicians of the state have been enrolled in courses given in ten cities of Wisconsin by the bureau of postgraduate medical instruction of the University of Wisconsin, Extension Division. These courses were given by Drs. Frederick C. Rinker and Hugh P. Groves, Madison, under the direction of Dr. L. Rock Sleyter, Wausau.

Antituberculosis Association in New Home.—The September issue of the *Crusader*, the monthly publication of the Wisconsin Anti-Tuberculosis Association, was issued from its new building, known as the Health Service Building on Jefferson Street. This building is now the headquarters of the organized fight against tuberculosis and preventable diseases, and for better health in Wisconsin.

CANADA

Banquet to Service Men.—The members of the Academy of Medicine, Toronto, will give a complimentary banquet to 150 of its Fellows who have served overseas, September 30. The Academy opens its regular session in October under the presidency of Dr. Edmund E. King, Toronto.

Six Years' Course Required.—With the opening of the session 1919-1920 of the medical department of the Western University, London, Ont., the course of medical studies will be six years, excepting that those matriculants who left for overseas service will be on the five-year plan. Toronto and Queen's Universities now pursue the same plan.

Personal.—Major W. Harley Smith, Toronto, has returned from overseas. In his three years' service he spent most of the time in the Orpington Military Hospital, but lately had been with an R. A. M. C. hospital in France.—Col. George G. Nasmyth, Ph.D., C. M. G., chief of laboratories in the department of health, Toronto, has resigned and will engage in consulting practice with a Toronto firm of sanitary engineers.—Mr. H. rare L. Brittain, Ph.D., who has been superintendent of the Toronto General Hospital for two or three years, has resigned. Mr. Brittain was engaged on the resignation of Dr. Charles K. Clarke, Toronto, to place the management on a business basis.

GENERAL

Southern Medical Association Meeting.—The annual meeting of the Southern Medical Association will be held at Asheville, N. C., November 12 and 13, with headquarters at the local Y. M. C. A.

Antimalaria Conference.—The American Anti-Malaria Association will hold a convention at Florence, Ala., Oct. 14-15, having as its object the launching of a campaign to eradicate malaria from the United States. Senator O. W. Underwood will be chairman of the convention.

Valley Physicians Meet.—At the seventeenth annual meeting of the Cumberland Valley Medical Association held at Hagerstown, Md., September 4, under the presidency of Dr. Percy D. Hoover, Waynesboro, Pa., Dr. Julia E. Fister, Hagerstown, Md., was elected president; Dr. David W. Van Camp, Plainfield, Pa., vice president; Dr. John J. Coffman, Scotland, Pa., secretary (re-elected), and Dr. John K. Gordon, Chambersburg, Pa., treasurer.

Medal to Dr. Noyes.—At a reception and dinner given by the Chicago Section of the American Chemical Society, September 26, the William Gibbs Medal, founded by William A. Converse, was presented to Dr. William Albert Noyes, director of the chemical laboratory of the University of Illinois. The presentation address was made by the president, William H. Nichols, and the Willard Gibbs address on "Positive and Negative Valences," by Dr. Noyes.

Röntgenologists Elect Officers.—At the recent annual meeting of the American Roentgen-Ray Society held at Saratoga Springs, N. Y., September 3-6, the following officers were elected: president, Dr. James T. Case, Battle Creek, Mich.; vice presidents, Drs. William P. Burnham, San Francisco, and Stanton Heck, Salem, Ohio; secretary, Dr. George W. Grier, Pittsburgh; treasurer, Dr. William A. Evans, Detroit; editor, Dr. Harry M. Imboden, New York City, and associate editor, Dr. Percy E. Brown, Boston.

Obstetricians and Gynecologists Elect Officers.—At the thirty-second annual meeting of the American Association of Obstetricians and Gynecologists held in Cincinnati, September 15 to 17, under the presidency of Dr. John F. Erdmann, New York, the following officers were elected: president, Dr. George W. Crile, Cleveland; vice presidents, Drs. Palmer Findley, Omaha, and David Hadden, Oakland, Calif.; secretary, Dr. E. Gustav Zinke, Cincinnati (re-elected), and treasurer, Dr. Herman E. Hayd, Buffalo. The next meeting will probably be held in Atlantic City, N. J., September 13 to 15, 1920.

Mississippi Valley Medical Association to Meet.—The forty-fourth annual meeting of the Mississippi Valley Medical Association will be held in Louisville, October 21 to 23, under the presidency of Dr. Francis M. Pottinger, Monrovia, Calif. The address in medicine will be given by Dr. Frank Smithies, Chicago, on "Cardio-Respiratory Manifestations of Gassing in Returned Soldiers," and the address in surgery by Dr. W. Wayne Balcock, Philadelphia. There will also be held symposiums on pneumonia, empyema, neuropsychiatry, surgery of bones, reconstruction problems, the treatment of the tuberculous soldier after his return to civil life, general surgical problems, the medical reserve officers in the war, and tuberculosis of the kidney.

Electrotherapeutists Hold Meeting.—The twenty-ninth annual meeting of the American Association of Electro-Therapeutists and Radiology was held in Philadelphia, September 16 to 19, under the presidency of Dr. William L. Clark, Philadelphia. The program included symposiums on dermatology, induced catabolism, metabolism, the cardiovascular system, roentgen therapy, digestive disturbances, orthopedics, reconstruction following war injuries and physiotherapy. The following officers were elected: president, Dr. William Martin, Atlantic City, N. J.; vice presidents, Drs. William T. Johnson, Philadelphia; Virgil C. Kinney, Wellsville, N. Y.; S. St. John Wright, Akron, Ohio; Mary L. H. Arnold Snow, New York, and John H. Burch, Syracuse, N. Y.; treasurer, Dr. Emil Heuel, New York (re-elected), and secretary and registrar, Dr. Byron Sprague Price, New York.

Label on Denatured Alcohol.—A recent circular, issued by the commissioner of internal revenue as a treasury decision, notifies revenue officers concerning a new ruling relative to the labeling of packages of completely denatured alcohol. This has been made necessary to protect ignorant users of these preparations. The notice states:

In view of the grave and extended abuse of the use of completely denatured alcohol reported, it is deemed necessary to print upon the label affixed to wholes and retail packages a further and more positive warning as to its use than is shown on the present required label.

In addition to the present matter on the labels there will be required on all new labels, hereafter the printing in large letters in red ink under the skull-and-crossbones symbol the word "Poison," and at the bottom of the label there will be printed the following statement:

"Completely denatured alcohol is a violent poison. It must be applied externally to human or animal tissue without seriously injuring results. It must be taken internally without inducing thinness and general physical decay, ultimately resulting in death."

Until the present stocks of labels are exhausted this additional matter may be affixed to the containers on a separate label pasted above the present required label.

Hygiene of Maternity and Infancy.—A bill to encourage instruction in the hygiene of maternity and infancy has been introduced in the United States senate by Senator Joseph T. Robinson of Arkansas. The bill provides that the children's bureau of the department of labor is to have general

supervision of the work, which will be directed by the federal government and carried on largely through state cooperation. The bill carries on appropriation of \$480,000, of which \$10,000 is to be granted to each state of the union for necessary expenses in carrying out the provision of the act, with larger appropriations for the next three subsequent years to be expended whenever any state offers to appropriate money for this work, the federal contribution being equal to that of the state. The state agency is to be the state board of maternity aid and infant hygiene, and after 1924 an annual sum of \$2,000,000 is provided. The general dissemination of information on maternity and hygiene is to be the chief function of the proposed enterprise. The bill has been referred to the senate committee on education and labor.

International Conference of Women Physicians.—This conference opened its sessions at the headquarters of the Y. W. C. A., New York City, September 15. The conference was assembled in response to new conditions created by the war under which good health became an asset to every woman as never before. Women physicians came to feel that they had a special contribution to make toward the development of the health of women and children. They have come to recognize that women must possess greater physical stamina if they are to make an effective contribution to industry and business without injury to the oncoming generation. With this idea in mind the subjects are being discussed by the conference, not from the research point of view, but from that of their practical bearing on the problem of the development of a more vigorous and responsible type of woman. The conference will continue with intermissions until October 15, when the results will be presented in condensed form to a convention of delegates from various women's organizations in this country and a proposed plan, by means of which women may bring to pass changes in social conditions affecting their lives as outlined in the previous program, will be discussed. During the intermissions, hospitals and institutions in and near New York will be visited and a trip to Boston has been arranged. Among the subjects discussed during the first week of the conference were "Health and Personality," "Physical Examinations as a Means of Health Education," "Exercise—Most Neglected Health Habit," "Dress as an Index of the Position of Women," "National Food Economics," and "Vitamins," the latter subjects being presented by Drs. Graham Lusk, New York, and E. V. MacCullom of Baltimore.

FOREIGN

Bard Called to Strasburg.—Prof. L. Bard, who for twenty years has been the incumbent of the chair of clinical medicine at the University of Geneva, has accepted a corresponding position at the University of Strasburg. He has published much personal research and deductions, his more recent works having been on the "sense of gyration," nystagmus, etc.

Germany's Losses in the War.—The *Deutsche medizinische Wochenschrift* of May 29 gives the total losses of Germany as 8,873,415. This includes the 615,922 soldiers held prisoners of war in other lands, and the 4,057,023 wounded. The dead numbered 1,676,650, and the missing, most of whom are presumably dead, 3,737,770, a total of 2,000,000 killed in the war.

Congress Number of the "Medicina Ibera."—The *Medicina Ibera* has issued a special number in honor of the First National Medical Congress in Spain. It gives full summaries of all the communications in the general meetings and the sections, with photographs of most of the speakers, and of operations, exhibits, etc. It also gives the resolutions adopted in the different sections and general meetings. The price is 8 pesetas. The daily papers of Madrid devoted large space to the congress, reproducing in full the principal addresses.

Typhus Fever in Spain.—In connection with the prevalence of typhus in Spain, it is stated that an epidemic of this disease developed in the provinces of Granada and Almeria in southern Spain. It was found that no delousing was being practiced, and that the disease was being spread by beggars traveling around. The Superior Board of Health sent a commission to those towns to organize the sanitary measures to be taken. Among these were the establishment of places to isolate these patients and of delousing plants, and the division of the affected provinces into two districts, each in charge of the representative of the Superior Board of Health. Since

this campaign was begun, the number of cases and deaths caused by the disease has decreased.

Overcrowding of the Profession at Vienna.—A letter in the *Deutsche medizinische Wochenschrift* for April 24 states that there are now 4,000 physicians in Vienna, while the highest number before the war was 2,800. In 1914, there were 6,223 deaths from tuberculosis; the record was 11,728 in 1918. The letter states further that the German Austrians lost 212 per thousand men between 19 and 53, while the Austrians of races other than German lost only 90 per thousand. The writer adds that every one in Vienna is hungry except the "Rote Garde." They are allowed 4,500 calories a day while the rest of the populace has to be content with 1,500 or 1,600. Even in the hospitals and other institutions no more than this is obtainable. There are still 30,000 dogs in Vienna, it is said, but there were 80,000 at the onset of the war; most of the others were stolen and eaten.

School Notes from England.—At a recent meeting of the London County Council Education Committee, it announced that three new open-air schools would be opened shortly, that sites had been acquired for seven such schools and that more are still contemplated. It was agreed that all schools shall be furnished with baths.—The committee has also under view the arrangements for the supply of spectacles for school-children.—The official return of the number of London children of the elementary school class shows a decrease of 41,994 in the last four years. The greatest proportionate decrease, 17,155, is in children between 3 and 5 years of age. For this abnormal decrease the outstanding reasons are said to be the decline in the birth rate during the past decade; the largely increased death rate during the year ended March, 1919; the migration of large families because of air raids and inability to return by reason of lack of housing accommodation and their replacement by smaller ones; the conversion of residential property into business premises; the fact that many families, owing to better financial prosperity, occupy more rooms than formerly, and the decrease in the East End alien population, owing to the restriction on immigration.

Government Services

Personnel of the Medical Department

For the week ending September 19, there were 6,242 officers in the Medical Corps, a decrease of 356 from the previous week. The Medical Reserve Corps contained 3,414. The total number of physicians discharged since the beginning of the war is 25,660.

Major-General Ireland Honored

Major-Gen. Merritte W. Ireland, Surgeon-General of the United States Army, has been made an honorary fellow of the Royal College of Surgeons of Edinburgh, Scotland. At the termination of the war the college offered honorary fellowship to one representative of each group of the medical forces of the British Empire and its allies, Major-General Ireland being selected as the American representative. Major-General Ireland has also been invited to deliver the "Ether Day" address, October 17, at the Massachusetts General Hospital.

Pensions for Civil War Nurses

All army nurses of the Civil War who are receiving a pension or who are entitled to it, would receive the sum of \$30 a month, under the terms of a bill introduced in the United States Senate by Senator James Curtis of Kansas.

Legislation to Commission Reserve Officers in Regular Corps

A bill to commission officers of the Medical Reserve Corps in the permanent Medical Corps of the regular army, provided the officers entered active service previous to April 6, 1917, and were within the prescribed age limit at that time and served honorably, has been introduced in the United States Senate by Senator Charles L. McNary of Oregon. A similar measure was recently introduced in the House of Representatives. The permanent commissions would date from the date of the reserve officer's entrance into active service.

Foreign Correspondence

MEXICO LETTER

Mexico, Sept. 14, 1919.

Classes of Clinical Medicine

The governor of the state of Puebla, De Cabrera, ordered the closing of the state college, in which one of the subjects taught was medicine. On this account, the students requested the director of the Military Hospital of that city to allow the teaching of clinical medicine in that institution. The director endorsed the request, and after being approved by the War Department, these classes have begun. It is probable that they will continue to be given as long as the state college remains closed.

Morbidity and Mortality

Judging from the report relating to the month of July, published by the state council, sanitary conditions in this city are satisfactory. There were recorded only 1,061 deaths, of which 309 were due to gastritis and enteritis, 62 to bronchopneumonia, 69 to tuberculosis, 51 to pneumonia and only 3 to typhus fever.

In the district known by the name of La Huasteca, which includes part of the states of Tamaulipas, Vera Cruz and San Luis, malaria has developed in an alarming way, attacking chiefly the soldiers fighting in that region. Typhoid fever has also made its appearance among the soldiers, and as the matter is very important from a military standpoint, the sanitary bureau of the War Department is devoting much attention to the eradication of these diseases.

According to newspaper reports there have been several cases of smallpox in the city of Vera Cruz.

Yellow fever is still present in the peninsula of Yucatan, although there is no definite information as to the number of new cases, or the deaths that have so far occurred.

Personal

Dr. Gregorio Leal died in the city of Managua, Nicaragua, where he had been sent by the Mexican government to establish a Pasteur Institute.—Dr. J. A. Gaxiola, who has the rank of general in the Mexican Army, has been visiting in Mexico City from Los Angeles, where he is now located.—Dr. E. Aragon, professor of legal medicine in the School of Medicine, has been sent by the government to Spain to represent Mexico in the *Fiesta de la Raza*, which will be held in Madrid on October 12.—Dr. C. Hidalgo has been elected president of the senate, and Dr. A. Méndez will act as speaker of the house of representatives during the present month.

Lymphocytosis Among the Syphilitic

Dr. T. G. Perrin has just published in pamphlet form an essay on the above subject presented by him on his admission to the Academy of Medicine. This work contains some

original observations, based on the study of 216 cases, in which there were made a white cell count and classification and the Wassermann, Jacobsthal and Kaplan reactions. Those cases in which the seroreaction is positive according to the first two procedures, or either of them, are considered syphilitic regardless of the clinical data. After recapitulating the conclusions reached on this subject by Patino, Mayer and Gourdy in the essay presented by them to the Academy of Medicine of Buenos Aires in 1915, and published afterward in *Los Progresos de la Clinica*, and those published by Blumberg in the *American Journal of Syphilis* in October, 1918, Perrin presents his conclusions, which are not in agreement with those of previous workers. In 79 of the 216 cases, the result of the serologic examination was positive, and negative in 137. Among the 79 with the positive reaction there was lymphocytosis only among 49. Among the 137 cases in which the serum reaction proved negative, 81 presented lymphocytosis. The author says that he publishes his conclusions, even if they do not show anything new, because they serve to show the exaggerated dependence placed on anatomopathologic data which may lead to error.

LONDON LETTER

LONDON, Aug. 27, 1919.

Medical Arrangements in the Afghan War

No sooner have the medical arrangements of the great war passed out of discussion than the question of those for one of the frontier wars, of which this country has had so much experience, has sprung up. The unexpected and unprovoked Afghan aggression led to mobilization of a large force, and the operations have revealed a considerable amount of unpreparedness with regard to medical arrangements. A serious feature was an outbreak of cholera, of which there were 1,663 cases at the end of July. There were 0.59 cases per cent. among the British troops and 0.88 among the Indian troops. There is no indication as to the place where the arrangements for water supply were defective. There were six separate lines of operations covering a front approximately 500 miles long. The local water supply was often by means of open irrigation channels, but piped water supply was installed in recognized camps. Cholera is endemic in the civil population in the whole area, and there were large numbers of recently enlisted transport and other followers without any water discipline or ideas of sanitation, and there was absence of supervision owing to shortage of experienced British officers. Arrangements for immediate supply of pure water in such a terrain were impossible to supervise in the case of troops compelled to march in conditions of abnormal heat. Yet the incidence of disease was very small among the British troops. Protective measures were initiated before the outbreak. A supplementary piped water supply was commenced, but the work was hampered by shortage of pumps and pipes demanded from England, Mesopotamia and elsewhere. Water for the troops was chlorinated. The wounded appear to have been well cared for. The majority of those wounded on the Aybala line were in the Station Hospital Peshawar, within a few hours of the action. At no time was there shortage of rations. It must be remembered that the Afghan outrage came on us at a time when the personnel and munitions of war in India had been reduced to the narrowest margin of safety to support the forces in the Near East and France. The desertion of the frontier militia and the threat of a rebellion in Peshawar deprived us of the measure of security on which we counted to cover our concentration. Consequently, instead of being able to proceed on a deliberate system of rapid concentration we had at once to send troops to every part of the frontier and reserve our prearranged plan which provided that the dispatch of stores and equipment should precede that of troops. As regards hospitals, there are no public buildings on the Indian frontier of India capable of immediate occupation. There was no alternative but the evacuation of barracks and their conversion into hospitals. This had been planned in peace time, but could not be rapidly carried out, especially during the hot weather. The medical service appears to have done everything possible in the midst of difficulties for which it was in no way responsible. There were, of course, discomforts in the rapidly improvised hospitals. The loss from sickness was very low considering the trying climate. The total admissions from May 15 to August 9 were at a rate of one thousand in 1,988 British and 20,972 Indian. The manner in which the cholera was suppressed is claimed as a triumph; 100,000 men were inoculated in one fortnight.

German "Science"

Mr. Adolphe Smith, a journalist who has represented the *Lancet* at many international medical congresses, has contributed to the *Times* a series of articles on the Pan-German Internationale. Since 1882 he has acted as official interpreter at all the social congresses called the "Internationale" and, therefore, writes with the authority of an eye witness. He shows that as the military caste of Germany worked for world dominion by arms, so Marx and his subordinate Engels worked for a similar end by obtaining control over the labor organizations of the world. To delude the forger, the German socialists declared themselves the enemy of militarism. But the war has shown that, with few exceptions, they supported German war aims while at the same time endeavoring to weaken the nations opposing Germany by fostering socialism among them. Mr. Smith found at the international medical congresses the same motives at work. At the International Medical Congress in London, in 1881, the Germans took a proper share as representatives of a nation of the first rank. There the great men were Pasteur, Lister, Paget, Bigelow and Virchow. But at the subsequent congresses the German professors became more and more overbearing, and their methods conflicted with the free spirit of scientific discussion. Mr. Smith writes thus: "It has been my privilege to attend nearly all the international congresses of hygiene, and several of the international congresses of medicine, of the medical press, of the war against tuberculosis, and of other kindred movements. Here, among members of the liberal professions as in working class congresses, the German delegation acted with the same military discipline. The science which they represented was a secondary consideration; the interests of Germany, the advertising of German achievements, not to say German goods, was the first object. In all fields of action the German as an internationalist needs to be studied with far greater care than as yet has been bestowed on him. We must no longer be deceived by the nominal purpose of a congress; the political interests that are hidden behind must be fathomed. Science is supposed to recognize neither frontier nor private interests, but to be devoted to the pursuit of truth. To the German it would appear as if the sole mission of science is to serve Germany. And this is pan-Germanism, not internationalism." Referring to the question of tuberculous meat, Mr. Smith puts the action of the Germans in a very sinister light. He writes: "The danger or otherwise of consuming tuberculous meat was of very material importance to the German agrarian party, for a large proportion of German cattle was known to be tuberculous. This party held office when at a great international scientific congress it was my good fortune to discover and to denounce intrigues that had for their purpose the adoption of a resolution exonerating the specific germ of bovine tuberculosis. This maneuver had been promoted by the German delegation and the official representatives of the German government." Mr. Smith is referring to the International Congress on Tuberculosis held at Washington in 1908, and his protest was published in the *Lancet* at the time. Commenting on his present series of articles, the *Lancet* recalls the sensation made by Koch's statement at the British Congress on Tuberculosis that the infection of human beings by bovine tuberculosis is very rare, and his pronouncement: "I should estimate the extent of infection by the milk and flesh of tuberculous cattle, and the butter made from their milk, as hardly greater than that of hereditary transmission, and I therefore do not deem it advisable to take any measures against it." The *Lancet* adds: "It was charitably supposed that the distinguished scientist had slipped into error. No doubt he had; but we may perhaps be forgiven for wondering if the exact nature of the error was correctly diagnosed at the time."

Marriages

HEINRICH EDMOND FRANCK, Sacramento, Calif., to Miss Anna Theresa Heilgers of Aachen, Germany, August 15.

THEODORE HIGGINS SWEETSER, Minneapolis, to Miss Marion E. Morrow of Davenport, Iowa, September 3.

VICTOR BAYARD SEIDLER to Miss Eleanor Dickson, both of Montclair, N. J., September 6.

ALBERT ZINGHER to Miss Anna L. Cherey, both of New York, September 7.

ANSON M. CAMERON to Miss Alta Stevens, both of Chicago, September 20.

Deaths

Benjamin Buck Wilson, Philadelphia; University of Pennsylvania, Philadelphia, 1850; aged 90; who at the outbreak of the Civil War, organized a military company in the village of Bustleton, was captain of U. S. Volunteers; organizer of the Alexander Hospital, New Orleans, and then in charge of the Stanton Hospital, Washington, D. C.; and was mustered out of the service at the close of the Civil War with the rank of lieutenant-colonel; from 1867 to 1883 surgeon to the Woman's Hospital, and professor of surgery in the Woman's Medical College of Pennsylvania, Philadelphia; for ten years surgeon to the Howard Hospital, and for more than thirty years a member of the surgical staff of the Jewish Hospital, Philadelphia; a member of the Association of Military Surgeons of the United States; died at his home, August 28.

Fred Perkins Lierle, Marshalltown, Iowa; Rush Medical College, 1894; aged 47; a member of the Iowa State Medical Society; and once secretary of the Marshall County Medical Society; a specialist in diseases of the eye, ear, nose and throat; consulting oculist to the Iowa State Soldiers' Home; oculist and aurist to St. Thomas' Hospital, Marshalltown; formerly local surgeon of the Illinois Central system; health officer of Marshalltown, and coroner of Marshall County; died in the Kenilworth (Ill.) Sanitarium, September 10, from pernicious anemia.

Joseph Aloysius Kenefick * New York City; Harvard University Medical School, 1890; aged 58; a member of the American Laryngological, Rhinological and Otolological Society, American Otolological Society and New York Academy of Medicine; formerly assistant surgeon to the Manhattan Eye, Ear and Throat Hospital; assistant laryngologist to Cornell University; aural surgeon to the New York Eye and Ear Infirmary, and otologist and laryngologist to the New York Foundling Hospital; died in Lawrence, Mass., September 10.

Henry Hooper * Chicago; Harvard University Medical School, 1869; aged 75; for half a century an esteemed and beloved practitioner of Chicago; emeritus professor of obstetrics in the Chicago Policlinic; obstetrician to Passavant Hospital, and St. Mary's Maternity Hospital for many years; treasurer of the Policlinic and Henroft hospitals; died at his home, September 17.

Jay Hobart Egbert * Willimantic, Conn.; Dartmouth Medical School, Hanover, N. H., 1891; aged 50; oculist and aurist to St. Joseph's Hospital, Willimantic; assistant surgeon to the eye department of Cornell University Medical College, New York; a member of the medical staff of the United Fruit Company; died in Lima, Peru, S. A., August 27, from ptomain poisoning.

Howard Kennedy Hill, Philadelphia; University of Pennsylvania, Philadelphia, 1903; aged 40; a member of the Medical Society of the State of Pennsylvania, and a specialist in pediatrics; a noted athlete and secretary of the Athletic Association of the University in 1907; died in the Presbyterian Hospital, Philadelphia, September 11.

Charles E. Congdon, Jamestown, Calif.; University of Louisville, Ky., 1894; aged 54; a member of the Medical Society of the State of California; formerly health officer of San Francisco County; died at San Francisco, September 6.

William Thomas Breeland, Allendale, S. C.; Medical College of the State of South Carolina, Charleston, 1850; aged 87; surgeon in the Confederate service during the Civil War; died at the home of his daughter in Laurens, S. C., August 20.

Ambrose Kasson, Bath, N. Y.; University of Buffalo, N. Y., 1873; aged 70; a member of the Medical Society of the State of New York; a specialist on diseases of the eye, ear, nose and throat; died at his home, September 1.

Job E. W. Smith, Waycross, Ga.; Vanderbilt University, Nashville, Tenn., 1882; aged 64; for several years chairman of the board of education of Waycross; died at his farm near that city, September 6, from cerebral hemorrhage.

Didymus Thomas, Oldtown, Tenn.; Hospital College of Medicine, Louisville, Ky., 1890; aged 50; died at his home, September 13, from the effects of a gunshot wound of the heart, self-inflicted, it is believed, with suicidal intent.

Clark T. Hamilton, Huntington, N. Y.; New York Homeopathic Medical College, New York City, 1865; aged 87; for

nearly forty years a practitioner of Brooklyn; died at the home of his son in Huntington, September 11.

Edwin E. Allison, Hammondton, N. J.; University of Pennsylvania, Philadelphia, 1895; a member of the local board of education; died in the Lankenau Hospital, Philadelphia, August 27, a week after a surgical operation.

John Milton Garratt * Buffalo; University of Buffalo, 1897; aged 54; a specialist in roentgenology; consulting roentgenologist to the J. N. Adam Memorial Hospital, Perysburg, N. Y.; died at his home, September 6.

Christian Christensen * La Crosse, Wis.; University of Christiania, Norway, 1879; aged 60; one of the founders of the Lutheran Hospital, La Crosse; died at his home, September 7, from carcinoma of the stomach.

Grove Heman Rathbun * Fremont, Neb.; University of Nebraska, Omaha, 1902; aged 38; who was honorably discharged as captain, M. C. U. S. Army, Dec. 23, 1918; died in Clarkson Hospital, Omaha, September 5.

Arthur Vincent Fray * Chicago; Jenner Medical College, Chicago, 1906; aged 55; a specialist in diseases of the eye, ear, nose and throat; died in St. Luke's Hospital, Chicago, September 7, from carcinoma.

John Richard McDurdo, San Francisco; University of California, San Francisco, 1891; aged 64; a member of the Medical Society of the State of California; died at his home, in August, from myocarditis.

Frank Morgan Storer * Wilkesburg, Pa.; University of Pittsburgh, 1899; aged 48; a specialist in surgery; assistant professor of anatomy in his alma mater; died at his home, September 9, from diabetes.

Levy Pierce Hammond, Rome, Ga.; New York University, New York City, 1880; aged 63; a member of the Medical Association of Georgia; died in St. Joseph's Hospital, Atlanta, Ga., August 25.

James Burriss Wood, Oakland, Calif.; University of Pittsburgh, 1892; aged 51; a member of the Medical Society of the State of California; died at his home, September 9, from pneumonia.

David Gootenberg * Staten Island, N. Y.; Cornell University Medical College, New York City, 1908; aged 32; died at his home in Stapleton, S. L., September 13, from heart disease.

Juliet H. Severance, New York City; New York Hygieo-Therapeutic College, New York City, 1857; aged 80; died at the home of her daughter in New York City, September 2.

James C. Cooper, Baltimore (license, Maryland, years of practice); aged 52; a practitioner for twenty-five years; died, August 20, on a yacht at Crisfield, Md., from acute gastritis.

Theodore S. Thomas * Cuba, N. Y.; University of Buffalo, 1882; aged 58; at one time health officer of Allegany County; died at his home, September 1, from heart disease.

Thurston H. Rowles, Bellaire, Ohio; Ohio Medical University, Columbus, 1890; aged 68; died at the home of his sister on Wheeling Island, September 6, from pneumonia.

Joseph A. Burgoon, Pittsburgh (license, Elk and Clarion Counties, Pa., 1877); aged 78; for fifty-six years a practitioner; died at his home, September 9.

Edwin Jay Fisk, Troy, N. Y.; Albany (N. Y.) Medical College, 1871; aged 70; city physician of Troy for eight years; died at his home, August 31.

Emma A. Whitney, Muncie, Ind.; Cleveland University of Medicine and Surgery, 1886; aged 64; died at her home, May 29; from carcinoma of the rectum.

John C. Helper, Woodriver, Ill.; Eclectic Medical Institute, Cincinnati, 1881; aged 61; died at the home of his daughter in Abilene, Kan., September 1.

George S. Gunderson, Milwaukee; Marquette University, Milwaukee, 1916; aged 32; died at his home, August 10, from cerebral hemorrhage.

William Steele Moat, Philadelphia; Hahnemann Medical College, Philadelphia, 1876; aged 79; died at his home, September 5, from peritonitis.

William O. Steels, Alliance, Ohio; University of Wooster, Cleveland, 1875; aged 60; died at the home of his son in Alliance, September 10.

James C. Alderson * Wausau, Wis.; Rush Medical College, 1897; aged 46; died at his home, August 17, from tubercular laryngitis.

T. B. Weir, Dayton, Tenn. (license, Tennessee, 1889); aged 63; died at his home near Dayton, August 16.

* Indicates "Fellow" of the American Medical Association.

therefore the detail men were told to "discontinue using the photographic copy in question" and to return the photographs to the head office.

Here, briefly, are the bald facts in the case. The essential point at issue is whether these photographic copies of Dr. Brocman's letter would or would not be likely—whether or not they were so intended—to mislead physicians into believing that the endorsement was an official one by the State Board of Health rather than an individual one. One can but wonder why, if, as the Merrell company so vehemently asserts, there was no intention of misleading physicians on this point, the company should have gone to the trouble and expense of *photographing* the entire letter, including the letterhead, rather than making typewritten or mimeographed copies of the *contents* of the letter.

THE DIRECT SALES COMPANY

During the past four or five years, THE JOURNAL has had inquiries similar in effect to this, just received from Dr. E. P. Jewett of Gardner, Mass.:

"Will you kindly inform me regarding a drug manufacturing company by the name of the Direct Sales Company, Buffalo, New York? Are their products standard and reliable so far as you know?"

The Direct Sales Company, Inc., Buffalo, has according to its letterheads, the following officers:

Geo. J. DOTTERWEICH, President and Treasurer,
C. K. DOTTERWEICH, Vice-President,
LOUIS B. SEUFERT, Secretary.

This concern circularizes physicians and emphasizes that it sells "Only by Mail." It also features a "profit sharing rebate" scheme whereby purchasers receive a coupon representing 10 per cent. of the invoice value of each purchase. After \$100 worth of merchandise has been purchased the \$10 worth of coupons when "presented for redemption at one time" will be "honored as cash"—presumably on the purchase of additional goods.

The Direct Sales Company catalogues have, for some years, carried a guaranty, which reads, in part:

"We absolutely guarantee all preparations to be in exact accordance with the National Pure Food and Drugs Act, June 30, 1906.

"We also absolutely guarantee all preparations bearing our label to be equal, if not superior, to any on the market."

In one of the *Quarterly Bulletins* of the State Board of Health of New Hampshire, issued last year, this paragraph appeared:

"The Direct Sales Company, Inc., Buffalo, N. Y., is a pharmaceutical concern which until recently has done business direct with New Hampshire physicians. In two or three instances complaints have been received by this department that the preparations sold seemed to be lacking in potency. Sometime ago a physician sent us a specimen of codein sulphate tablets, one-fourth grain, concerning which he was suspicious, admission being made that the price paid was very much less than current quotations. The amount of codein sulphate actually found per tablet proved to be but one-sixteenth grain. Later on, having subsequently received a new lot from this source, the same physician sent us a second sample, the composition of which was found to be practically identical with the first. Acting under the federal law, 500 lot packages of the following preparations were next purchased of the company direct, the analytical results indicating serious deficiency in every case, as follows:

"Tablets salicylic acid, 5 grains . . . 1.72 grains found.

"Tablets acetylsalicylic acid, 5 grains . . . 2.31 grains found.

"Tablets acetanilid, 3 grains . . . 1.88 grains found.

"Tablets codein sulphate, $\frac{1}{4}$ grain . . . $\frac{1}{15}$ grain found.

"Tablets nux and pepsin No. 2, claiming pepsin 1 grain, extract nux vomica, $\frac{1}{10}$ grain, found to have a gross average weight per tablet of only 1.17 grains, 0.54 grains of which was represented by sugar and other medicinally inert material.

"Tablets Infant's Anodyne (Waugh), showed serious discrepancy from formula."

The *Bulletin* added the statement that, as the company could not be reached under the New Hampshire laws, the federal authorities were appealed to. The result of this appeal appeared in *Chemical Supplement 54*, issued Aug. 21, 1918, by the Bureau of Chemistry of the U. S. Department of Agriculture. This government bulletin contained Notice of Judgment No. 6193, which describes cases of adulteration and misbranding of some of the drugs put out by the Direct Sales Company. Briefly, it may be said that some 2 grain acetanilid tablets sold by this concern were found by the government chemists to contain, roughly, about 1 $\frac{1}{2}$ (1.61) gr.; some $\frac{1}{4}$ grain calomel tablets were found to contain only about $\frac{1}{8}$ (0.163) gr.; some 1 grain quinin sulphate tablets were found to have only about $\frac{2}{3}$ (0.63) gr.; some 2 $\frac{1}{2}$ grain salol tablets contained only about 1 $\frac{1}{2}$ (1.39) gr.; some 5 grain sodium salicylate tablets contained less than half that amount (2.32 gr.). In addition, the federal chemists found that some Elixir of Iron pyrophosphate Quinin and Strychnin (*Elix. Ferr. Pyrophosph. Quin. et Strych. N. F.*) fell considerably below the standard of strength laid down by the National Formulary by having less than $\frac{1}{2}$ the amount of quinin sulphate which the official standard calls for, and only about $\frac{1}{2}$ the amount of sugar, saccharine, which is not a normal ingredient of the official preparation, having been substituted for part of the sugar. The chemists found, too, that some hydriodic acid sold by the same concern, instead of containing, as the label declared and as the United States Pharmacopoeia requires, 1 per cent. of absolute hydriodic acid, contained less than one half of 1 per cent. The Direct Sales Company pleaded guilty in this case and was fined \$700.

Correspondence

PNEUMONIA AMONG PORTO RICAN LABORERS

To the Editor:—It was with interest that I read in THE JOURNAL, July 19, 1919, an article entitled "Type 1 Pneumococcus Among Porto Rican Laborers." The summary states that "Porto Ricans under favorable conditions are susceptible to lung infection by the Type 1 pneumococcus. The disease pursues a typical course, accompanied by a bacteremia in about the same proportion as among white persons."

Do the authors of the article wish to exclude all Porto Ricans from the white race, or may we take it as a lack of information? Mr. Fred K. Fleagle, dean of the University of Porto Rico some years ago, who has lived in this island for a number of years, has said: "The island of Porto Rico, covering an area of 3,500 square miles, had in 1910 a total population of 1,118,012. The population is as follows: pure white persons, 65.5 per cent.; mulattoes, 30 per cent.; black, 4.5 per cent. It is 98.9 per cent. native and 1.1 per cent. foreign born." I here add that the Porto Rican laborers who availed themselves of the magnificent opportunity to go to the expedition and that were fortunate enough to be treated medically by the writers were for the most part negroes or mulattoes. Concerning the white part of the population, they are thoroughbred, and the best Spanish blood runs through their veins; many are of noble descent.

I object to the generalization, and beg that a correction be made.

C. M. DEL VALL, M.D., Santurce, San Juan, Porto Rico.

"ABDOMINAL SURGERY UNDER LOCAL ANESTHESIA"

To the Editor:—In THE JOURNAL, Sept. 6, 1919, Dr. Lucius F. Herz of New York criticized the pneumatic injector that I devised for the introduction of local anesthesia. He asks why such a "complicated" apparatus as mine is necessary, and he furnishes an illustration of an apparatus which he states will obtain the same results. He then asks "what could be simpler or what can be more beautifully efficient" than the apparatus he illustrates. In answer, I would say

that many years of careful experimentation and practice have shown that a pressure of from 30 to 75 pounds is necessary to introduce local anesthesia solutions into the various tissues through a long, fine needle.

Dr. Herz states that this can be done with his instrument. In order to do so, I believe he would have to substitute for his ounce bottle filled with mercury at least a keg of nails. Briefly, the apparatus which he illustrates was the first model used by me some fifteen years ago. It was discarded, not because it was too simple, as simplicity is much to be desired, but for the reason that it was inefficient.

ROBERT EMMETT FARR, M.D., Minneapolis.

DR. NOGUCHI AND THE WASSERMANN TEST

To the Editor:—On page 635 of THE JOURNAL, Aug. 23, 1919, appears a statement credited to me to which I should like to invite attention because as it stands it is very misleading. The statement should read: "I have been able to increase the sharpness of the reaction nearly four times by using a slowly mixed (turbid) emulsion of acetone insoluble lipoids as antigen."

HIDEYO NOGUCHI, M.D., New York.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

VACCINE AS A PROPHYLACTIC IN INFLUENZA

To the Editor:—I am chief surgeon for a large steel industry in Canton, and desire to do all in my power to prevent the threatened recurrence of influenza. What is the status of the various vaccines as a preventive or prophylactic measure? Would you advise their use as a preventive measure, to immunize the workers in the industries?

M.D., Canton, Ohio.

ANSWER.—The status of vaccine therapy as a prophylactic for influenza may be ascertained from the two articles appearing in THE JOURNAL, Aug. 9, 1910: that of E. C. Rosenow and B. F. Sturdivant entitled "Studies in Influenza and Pneumonia: Further Results of Prophylactic Inoculations," and that of G. W. McCoy, director, Hygienic Laboratory, U. S. Public Health Service, on "Status of Prophylactic Vaccination Against Influenza." In brief, the conclusion of Rosenow and Sturdivant is: "It appears from all of the facts at hand that by the use of a properly prepared vaccine it is possible to rob influenza of some of its terrors." On the other hand, McCoy states: "The general impression gained from uncontrolled use of vaccines is that they are of value in the prevention of influenza; but, in every case in which vaccines have been tried under perfectly controlled conditions, they have failed to influence in a definite manner either the morbidity or the mortality." To make a conservative statement, "The use of vaccine as a prophylactic in influenza is an experiment."

PASTEUR LABORATORIES RAT VIRUS

To the Editor:—Can you give me information as to the organism used in the rat bite. It is a Dancysz virus or the similar preparation put out by the Pasteur Company. I have been unable to find reference to this method of exterminating rats in the literature at present.

D. H. DANCY, Columbus, Ohio.

ANSWER.—We presume by "Pasteur Company" our correspondent means the Pasteur Laboratories of America, a New York concern which advertises a preparation for the scientific extermination of rats and mice, stating: "It is distributed on bait and causes a contagious and mortal disease that only affects rodents. Both the virus and disease are harmless to domestic animals, pets, game, poultry and man."

According to Jordan ("General Bacteriology," 1918, p. 295), Dancysz ("Ann. de l'Inst. Pasteur," 1914, p. 1943) isolated this organism from an epidemic among harvest mice. The organ-

ism belongs to the colon typhoid group of bacilli. Under the name of Dancysz virus it has been widely used in attempts to exterminate rats. The virus does not seem to be readily transmitted from rat to rat under natural conditions, and Jordan believes that its practical value is not so great as often claimed. It cannot be said to be altogether harmless to man. McFarland ("Pathogenic Bacteria and Protozoa," 1916, p. 630) states that this organism "is, however, too uncertain in action to be relied upon for destruction of rats."

GASOLINE INTENSIFIERS—TANKII TABLETS

To the Editor:—I am enclosing an advertisement which I want to bring to your notice and wish you would reply in THE JOURNAL as to the value of these preparations. Kindly omit name.

C. K. J., Burlington, Vt.

ANSWER.—The advertisement carries the statement that "Tankii contains neither acid, alcohol, ether or camphor" and tells how "Dr. F. T. Kidder" received much power from the gasoline in which he used Tankii. Several years ago, the North Dakota chemists analyzed these tablets and found them "to consist essentially of naphthalene perfumed with oil of citronella" (Gasoline Savers, the *Druggists Circular*, July, 1916, p. 416). Naphthalene is also the essential constituent of other tablets for addition to gasoline, among them being "cheap gas" and "Inajiffi" (THE JOURNAL, Sept. 16, 1916, p. 897). In *The Chicago Chemical Bulletin* (July, 1918, p. 143) an abstract of the annual report of the director of the Bureau of Standards concerning gasoline intensifiers, stated:

There are a number of materials on the market known as gasoline intensifiers for which the claim is made that when added in small quantities to gasoline, an increased engine efficiency is secured. Six of these materials were tested with a six cylinder automobile engine driving an electrical absorption dynamometer. A sample of gasoline alleged to be treated by a secret electrochemical process was tested in the same way. The apparatus used was very sensitive and capable of indicating small differences in power developed, but in no case was there any noticeable increase in power or efficiency of the engine when using the treated gasoline, as compared with its performance when using straight gasoline under the same operating conditions.

As THE JOURNAL has stated previously, naphthalene, because of its high carbon content, when dissolved in gasoline, does add some energy; but its solubility is so low that the gain is negligible. Certainly the addition of the few tablets recommended is so small that the effect would not be noticeable. Furthermore, if the addition of the small quantity did produce appreciable augmentation of energy, why not buy naphthalene in the form of "moth balls"? A further disadvantage of naphthalene in explosion engines was pointed out by F. W. L. Tylderman (THE JOURNAL, Oct. 14, 1916, p. 1174).

DRESSING FOR LABORATORY TABLES

To the Editor:—Some time ago, if I am not mistaken, there appeared in this department of THE JOURNAL a description of a method for finishing the tops of laboratory desks. Can you supply me with the formula?

D. W. CARTER, JR., M.D., Dallas, Texas.

ANSWER.—As considerable time has elapsed since we published the formula for an etching preparation to render laboratory tables resistant to staining or corroding chemical reagents we repeat it herewith:

Solution A:	
Copper sulphate and potassium chlorate, each	125 gm.
Water	1,000 gm.
Boil till salts are dissolved.	
Solution B:	
Anilin hydrochloride	150 gm.
Water	1,000 gm.
or:	
Anilin	120 gm.
Hydrochloric acid	180 gm.
Water	1,000 gm.

Two coats of Solution A are applied while hot, the second as soon as the first has dried. Two coats of Solution B are applied, and the wood is allowed to dry thoroughly. Next a coat of raw linseed oil is rubbed in by means of a cloth to give a polish. In the treatment with the oil, the deep black color is partially brought out, but this does not uniformly appear until the table has been thoroughly washed with hot soapsuds. The latter treatment removes superfluous chemicals. To keep the table in condition, it is said to be necessary only to wash off occasionally with soap and water and then to rub with oil. The amount is sufficient for 10 square yards of surface.

COMING EXAMINATIONS

ARIZONA: Phoenix, Oct. 7. Sec., Dr. Allen H. Williams, 219 Goodrich Bldg., Phoenix.

ARKANSAS: Little Rock, Nov. 11-12. Sec. Regular Board, Dr. T. J. Stout, Pinkley Sec. Elective Board, Dr. Claude E. Laws, 803½ Garrison Ave., Fort Smith.

CALIFORNIA: Sacramento, Oct. 20-23. Sec., Dr. Chas. B. Pinkham, Butler Bldg., San Francisco.

COLORADO: Denver, Oct. 7. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

CONNECTICUT: New Haven, Nov. 11-12. Sec. Regular Board, Dr. Charles A. Tuttle, 196 York St., New Haven. Sec. Homeopathic Board, Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven. Sec. Elective Board, Dr. James E. Hain, 730 State St., Bridgeport.

DISTRICT OF COLUMBIA: Washington, Oct. 14-16. Sec., Dr. Edgar P. Copeland, The Rockingham, Washington.

GEORGIA: Atlanta, Oct. 14-15. Sec., Dr. C. T. Nolan, Marietta.

IDAHO: Boise, Oct. 7. Hon. Robt. O. Jones, Commissioner of Law Enforcement, Boise.

KANSAS: Topeka, Oct. 14. Sec., Dr. H. A. Dykes, Lebanon.

LOUISIANA: New Orleans, Nov. 4. Sec. Regular Board, Dr. E. W. Mahler, 141 Elk Place, New Orleans. Sec. Homeopathic Board, Dr. F. H. Hardenstein, 702 Maclure Bldg., New Orleans.

MAINE: Portland, Nov. 11-12. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

MICHIGAN: Lansing, Oct. 14-16. Sec., Dr. B. D. Harrison, 504 Washington Arcade, Detroit.

MINNESOTA: Minneapolis, Oct. 7-9. Sec., Dr. Thos. McDavid, 741 Lowry Bldg., St. Paul.

MISSOURI: Kansas City, Oct. 7-9. Sec., Dr. Geo. H. Jones, State House, Jefferson City.

MONTANA: Helena, Oct. 7. Sec., Dr. S. A. Cooney, Power Bldg., Helena.

NEBRASKA: Lincoln, Nov. 12-14. Sec., Dr. H. J. Leimbach, 514 First Nat'l Bank Bldg., Lincoln.

NEVADA: Carson City, Nov. 3. Sec., Dr. S. L. Lee, Carson City.

NEW JERSEY: Trenton, Oct. 21-22. Sec., Dr. Alexander MacAlister, State House, Trenton.

NEW MEXICO: Santa Fe, Oct. 13-14. Sec., Dr. R. E. McBridge, Las Cruces.

OKLAHOMA: Oklahoma City, Oct. 7-8. Sec., Dr. J. J. Williams, Weatherford.

RHODE ISLAND: Providence, Oct. 2-3. Sec., Dr. B. U. Richards, State House, Providence.

SOUTH CAROLINA: Columbia, Nov. 10. Sec., Dr. A. Earle Bouzer, 184½ Hampton St., Columbia.

UTAH: Salt Lake City, Oct. 6-7. Sec., Dr. G. E. Harding, Templeton Bldg., Salt Lake City.

WEST VIRGINIA: Charleston, Oct. 14. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

WYOMING: Cheyenne, Oct. 6-8. Sec., Dr. J. D. Shingle, Cheyenne.

California March Examination

Dr. C. B. Pinkham, secretary of the Board of Medical Examiners of the State of California, reports the oral and written examination held at Los Angeles, March 17-20, 1919. The examination covered 9 subjects and included 90 questions. An average of 75 per cent. was required to pass. Of the 59 candidates who took the physician's and surgeon's examination, 26, including 12 osteopaths, passed, and 33, including 8 osteopaths, failed. Three candidates were licensed on Army and Navy credentials. One hundred and four candidates were licensed through reciprocity. Five candidates were granted osteopathic reciprocity licenses. Two candidates were granted drugless healer licenses, two candidates received drugless healer reciprocity licenses, and one candidate was granted a license to practice chiropody. In the physicians's and surgeon's examination the following medical colleges were represented:

College	PASSED	Year Grad.	Per Cent.
California Eclectic Medical College	1	(1918)	75
College of Phys. and Surgs., San Francisco	1	(1918)	75.5

Book Notices

THE CHEMISTRY OF SYNTHETIC DRUGS. By Percy May, D.Sc., F.I.C. Second edition. Cloth. Price, \$3.50. Pp. 250. New York: Longmans, Green & Co., 1918.

Since the first edition of this book appeared in 1911, great advances have been made in our knowledge of the pharmacology of synthetic chemicals, especially in the relationships which certain groups of atoms (organic radicals) bear to physiologic effects. This has led to new therapeutic applications for chemical substances already well known, and to a search for new substances whose therapeutic properties, like their physical characteristics, might be predicted to a considerable extent from the theoretical composition. Before the opening of the world war, most synthetic medicinals were made in Germany, and soon after the war began, a serious shortage in supplies of synthetic drugs developed. This shortage soon stimulated an interest in their manufacture and perfection both in Great Britain and in the United States. The results are reflected in the new edition of this book, which describes many drugs not mentioned in the earlier one. Among these are acriflavine and proflavine; anesthetics; cinchophen (atophan); brilliant green; procain and surgical solution of chlorinated soda (Dakin's solution). Also new nonproprietary names are used in place of the German proprietary titles. Examples are barbitone for veronal (barbital, N. N. R.) and kharsivan for salvarsan (arsphenamin, N. N. R.). The chemical nature and method of preparation for many synthetics are described, and attention is given to the reactions taking place between the living organism and the drug wherever these can be traced. The relations between the chemical character of a substance and its pharmacologic action are discussed. Physicians, teachers and students in pharmacology will find this an excellent reference work.

INTRAVENOUS INJECTION IN WOUND SHOCK: BEING THE UNIVERSITY LECTURES DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON IN MAY, 1918. By W. M. Bayliss, M.A., D.Sc., F.R.S., Professor of General Physiology in University College, London. Cloth. Price, \$3 net. Pp. 172, with 59 illustrations. New York: Longmans, Green and Co., 1918.

The importance of the problem of surgical shock as the result of surgical procedure in time of peace has long been recognized. Renewed interest in an experimental study of its causation and treatment was the result of the past war. Clinicians made a careful study of the abundant material, while laboratory workers searched anew for its cause and devised measures to combat the condition. The results of the latter investigations are incorporated in the present volume in the form of two lectures by Professor Bayliss, chairman of the Special Committee for the Investigation of Surgical Shock and Allied Conditions. Whereas Bayliss admits that the primary cause is still unknown, he feels certain that the most obvious sign of the condition, namely, the low blood pressure and the consequences that result therefrom, must be combated by the best means available after other factors that contribute toward its production (cold, absorption of tissue poisons, deficiency of oxygen) have been counteracted. To counteract the progressively sinking and fatal drop in the general arterial blood pressure the transfusion of human blood is of the greatest value; but since human blood is not available in large quantities (especially during battle) and must be previously tested for its compatibility with the recipient, he turns to the various types of artificial solutions that have been used, and the collected experimental evidence as to their efficacy in cases of surgical or wound shock in which they were tried. The major portion of the first chapter deals then with an evaluation of ordinary saline, Ringer's solution, hypertonic salt solutions, calcium

salts, solutions of sodium bicarbonate, and solutions of glucose. Finding them all of no lasting value in raising the arterial blood pressure and maintaining it at a raised level, he turns (Lecture II) to various solutions containing colloid; and finding certain of these solutions of colloid inefficient or even dangerous, he finally presents at great length the wonderful efficacy of gum arabic in physiologic sodium chlorid solution in shock and low blood pressure from other causes. From the perusal of this book it would appear that a most powerful antidote to combat the low blood pressure and its results had been discovered in the appropriate transfusion of gum solutions. Unfortunately, not all surgeons are agreed on the efficacy of such transfusions; for one clinician (Bernheim) has recently stated in a discussion appearing in *THE JOURNAL* (July 19, 1919, p. 181) that he had "never found a man who had any good to say of it. There are men in this audience whose experience with it proved disastrous. Certain men here have seen deaths from it. It not only did not help, it killed men." If Bernheim reflects the conviction of a great many men who have used gum solution, the chief treatment for shock about which a book was written must be subjected to further experimentation by investigators other than those whose studies, according to Bernheim, "were, apparently, not carried out with an open mind, that overwhelming evidence against the solution was not sufficient to cause its abandonment, instead of promoting futile efforts to improve it" (p. 173). At any rate, a very good outline of the past and present views as to the causation of shock is admirably presented. Aside from the value of the gum treatment of the condition, every surgeon will find the book interesting and instructive. It furthermore contains the most important bibliographic references on the subject.

THE WHOLE TRUTH ABOUT ALCOHOL. By George Elliot Flint. With an Introduction by Dr. Abraham Jacobi. Cloth. Price, \$1.50. Pp. 294. New York: The Macmillan Company, 1919.

In spite of the title, which promises by suggestion an impartial discussion of the entire alcohol question, we soon find that our author, the son of Dr. Austin Flint and himself a layman, needs to learn considerably more plain everyday human physiology and also the specific pharmacology of alcohol, before he can begin to discuss his chosen subject. The book certainly contains every talking point that has been raised in favor of the moderate consumption of alcohol. Furthermore, it is plain that on every controversial point the author mentions only evidence favorable to his standpoint. Finally, he sometimes quotes confidently as fact what is absolutely not true. It is the half truth about alcohol presented by one outspokenly in favor of its moderate use. The arguments are often based on incorrect premises leading the educated layman (for whom it was probably written) to accept the false conclusions. The author either lacks the fundamental physiologic and pharmacologic training and knowledge necessary really to discuss his theme as he proposes it in his title, or he avoids using them. The book is written in short, snappy paragraphs, which sustain the interest to the end.

A TREATISE ON ORTHOPEDIC SURGERY. By Royal Whitman, M.D., M.R.C.S., F.A.C.S., A Director of Military Orthopedic Teaching. Sixth edition. Cloth. Price, \$7. Pp. 914, with 767 illustrations. Philadelphia: Lea & Febiger, 1919.

This edition of Whitman fully maintains the high character that we have learned from previous editions to associate with this work, and quite justifies the imposing inverted typographic trapezoid on the title page containing the list of titles, positions and affiliations attached and subjoined to this distinguished author's name. The conventional classification used in former editions is also used in this one with the addition of a new chapter, No. XXIV, on military orthopedics. This chapter gives very fully the rules of selective service governing orthopedic disabilities, and then takes up the official list of conditions belonging to the orthopedic service mapped out and practiced during the war and subsequent reconstruction. Besides this new chapter practically every section has new and added information. There is no better textbook on orthopedic surgery in any language. The publishers' work is up to their usual high standard.

Social Medicine, Medical Economics and Miscellany

THE AMERICAN MEDICAL ASSOCIATION DESCRIBED FOR ITALIAN READERS

The *Riforma Medica* for June 21 contains an interesting letter from its New York Italian correspondent, most of which is devoted to the medical profession of the United States, but especially to the American Medical Association and its work. From the letter we quote:

"... In the medical field, all the intelligence, high grade character and worth of the physicians of the United States has taken concrete form in the institution of the largest and most powerful organization of professional men known in any land. It is not possible to study any medical happenings or any medical manifestation in America without seeing evidence everywhere of the marvelous work accomplished by this Association. In fact, it is difficult to find words to express in a fitting manner all that the American Medical Association has accomplished. Those who conceived the broad plan of the Association, who effected its organization, and who have since maintained it on an ever higher level, deserve not only most enthusiastic and sincere praise, but the gratitude as well of the medical profession of every country, for the great good that the American Medical Association has done and will do in the future, exerting a beneficial influence throughout the world.

"In succeeding letters I will speak more in detail of the work of the Association, but I trust that this brief outline will bring home to the readers of *La Riforma Medica* the great significance of this American organization and to give them some insight at least into the peculiarly ingenious methods which have been employed by it in exerting its enormous influence for good. At present I merely give an account of the fight which has been waged against the 'patent medicine' evil and for the improvement of American schools of medicine."

He then describes the unrestricted production of nostrums in America and the blatant advertising, and tells how the American Medical Association bought samples in the market and had them examined and tested, and accused the manufacturers of fraudulent practices as the medicines or the apparatus proved to be different from what was announced in the advertisements and failed to produce the results claimed. "Manufacturers now cannot advertise their promised miraculous cures without being liable to penalty. They have to keep their statements within bounds, and they do not attract the attention of the public as formerly. A large part of the stock of remedies, electric belts, and the like emigrated from America and invaded the European market."

"Of a higher order, from a constructive standpoint, though none the less radical, has been the campaign which has been carried on so vigorously for the improvement of medical education. In another article, at no distant date, I will show that certain of the American schools of practical medical science are models, such as can be found in no other country. There were formerly in America an enormous number of so-called medical schools that were absolutely unworthy of the name. They existed solely for the benefit of a few exploiters. . . . To have organized a campaign in the direction of bringing about a modification of the existing laws so as to bring pressure to bear on these institutions would not have been prudent, for the reason that it might have given the impression that certain schools were trying to monopolize medical instruction to the detriment of other schools and of science in general.

"The American Medical Association adopted a more effective and a more ingenious system which, besides demonstrating a marvelous spirit of cooperation, showed that the Association was not inspired by a desire for forcible measures no matter how well justified, but merely wished to appeal to the scientific sense and the honest judgment of American medical men. It began by organizing a council of unprejudiced men, who, by their mental attainments, personal en-

ture, and knowledge of conditions in foreign countries, gained by comparative study, were competent for the task before them. This council formulated a standard to which all medical schools should measure up. According as the various medical schools and colleges corresponded to the standard adopted, they were classified as A, B and C schools, and changed to higher grades as they came to conform to the standards. . . . By this means, while upholding the principle of absolute liberty, the Association, in a few years, accomplished the most marvelous results, succeeding in doing away, to a great extent, with the low-standard schools. Of course, it is impossible to destroy utterly an evil which is so solidly entrenched while the public is heedless. . . . I want the Italian medical profession to know that here in America there is a very powerful medical organization which is animated by the highest and most helpful ideals, the American Medical Association. It is always on the alert and always ready to strike, using the weapons of science, with the vigorous support of the honest medical press, and, above all, of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, in case the tentacles of the octopus try to work into action again."

Editorial comment on the letter mentions that one of the tasks proposed by the recently organized *Federazione generale medica italiana* is to keep up this same continual vigilance over the standards in the medical departments of the Italian universities. Many question whether the state and the nation will permit any interference with official educational methods, but the editor declares that the state and nation will be compelled to permit it when the entire body of medical men in the country in one powerful organization demand it and their demands are backed up by the universal recognition of the exalted motives for their action.

RAT EXTERMINATION

In Public Health Bulletin 103, published by the United States Public Health Service, arguments are presented for the elimination of the rat, and methods are given for its destruction. Investigation of the habits of the rat fail to show any justification for its continued existence in civilized communities. In other ages and under different sanitary conditions than now exist, it may have been of some service as a scavenger; but today it would seem to be of little, if any, use even in this capacity. It is impossible to do more than guess at the rodent population of the United States, but a conservative estimate is that there are as many rats in the United States as there are human beings, or over a hundred million. The cost of maintenance is estimated at half a cent a day each, or about \$182 a year per rat, so that the annual board bill of our rodent population would approximate \$182,000,000. This estimate, we presume, does not include property damage.

There are three varieties of rats in American cities, the most common of which is the brown rat, variously known as the Norway rat, barn rat and gray, or wharf rat. The other two varieties are the black rat and the roof, or Alexandrian rat. Owing to the antagonism and the superior fighting quality of the brown rat, however, the two latter species are rarely found in the United States except at seaports. Rats are not native to the United States. They are very prolific, the female rat producing from three to five litters a year, averaging eight to a litter. They are essentially burrowing animals, and live and breed by preference in excavations. They will burrow through any kind of soil and almost through any kind of building material except cement.

Articles damaged by rats include all kinds of grain before and after harvest; eggs and poultry; fruits and vegetables, both growing and stored; flowers, bulbs and shrubbery; all kinds of staples in bags or boxes; all food products in pantries, groceries, meat markets, bakeries, stables and general markets. In addition to food articles, rats also destroy leather goods, books, papers, clothing and fabrics. Some depredations committed by rats are almost unbelievable. Lantz, in Public Health Bulletin 30, reports an Iowa farmer who lost in one winter 500 bushels of corn; another farmer

who lost in one summer between 300 and 400 chicks; and a Washington merchant from whose stores rats in a period of two weeks carried away seventy-one dozen eggs. Rats are transmitters of bubonic plague, tapeworm, trichina and other diseases.

Rat destruction can be successfully carried out in a large city only by the compulsory rat proofing of buildings. They can be destroyed by trapping or poisoning or by the use of cats and dogs. Most authorities agree that all methods except rat proofing are of doubtful value, as partial destruction produces only more favorable conditions for propagation. In rat proofing any building, complete protection of the entire building must be observed, as the smallest opening will permit any building to become badly rat infested. Buildings may be rat proofed either by elevating the structure with open underpinning or by sinking marginal walls of concrete, stone or bricks laid in cement mortar 2 feet into the ground, fitting flush with the floor above. Rat proofing by elevation is applicable only to small buildings. In addition to rat proofing walls, all light shafts, ventilators and open windows should be wire screened, garbage should be kept in a metal water-tight can having a closely fitting lid, and the ground around the building should be kept clean and free from rubbish and devoid of rat harborage in the form of plank walks and plank covering. Rat proofing laws to be effective should provide explicitly the kind of concrete, thickness of floors and other details, as an ineffective rat proofing ordinance is more dangerous than no regulation, since it leads to a feeling of security without adequate protection.

MENTALLY DEFECTIVE CHILDREN IN SUSSEX COUNTY, DEL.

The U. S. Public Health Service and the Children's Bureau have completed a medicopsychologic and social study of mentally defective children in Sussex County, Del., the results of which appear in Pamphlet 7 of the Dependent, Defective and Delinquent Classes Series, Bureau Publication 48. The Public Health Service made mental examinations of children in the schools and of all inmates of the county almshouse. The Children's Bureau made a general survey for the purpose of locating mentally defective children not in the schools, and a social study of the conditions surrounding the children who were diagnosed as mentally defective.

The population of Sussex County for 1910 was 46,413, including 38,475 white persons and 7,938 negroes. The white population consisted chiefly of Americans of English descent. The population is scattered and rural in character. The leading industry is agriculture, the chief products being cereals, vegetables and fruits. The percentage of illiteracy is high, being 10.6 for the county as compared with 8.1 for the state. The county poor house is the only public institution. No outdoor relief is given. Of the thirty-five inmates of the county poorhouse, only three were found to be normal mentally, ten being diagnosed as feeble-minded. Six thousand and four white and 855 colored schoolchildren were examined. Sixty-seven, or 11 per cent., of white children were found to be mentally defective, and twenty-nine, or 3.4 per cent., of colored children. Nineteen white children and fifteen colored children not in the school were found to be feeble-minded, giving a total of eighty-six white and forty-four colored mental defectives. One hundred and eighty-one persons were found mentally defective in addition to those found in the schools and the poorhouse. In all, 257 cases of mental defect were identified. Of the children, 14 per cent. were unable to attend their own personal wants; 66 per cent. were able to help themselves and had no physical handicap. The remainder presented varying degrees of disability. One hundred and fifty, or 78 per cent., of the children lived with their own families, while 22 per cent. were cared for by relatives, foster parents or the public authorities.

Regarding the economic status of the families, fifty-four of the seventy-three white fathers were farmers, two-thirds of them being tenants or farm laborers. Practically all of the colored fathers were tenants or farm laborers. The mentality of the parents varied. In seven families having

thirteen mentally defective children, one or both parents were feeble-minded. In twenty-eight families, eighteen white and ten colored, one or both parents were classed as illiterate. These twenty-eight families had forty-seven feeble-minded children. Thirty-nine per cent. of the white children and 55 per cent. of the colored were capable of doing work under supervision, although the work performed was unskilled and simple in character. Of 144 mental defectives between 12 and 20 years of age, sixty-five were doing independent work or working under supervision. A number of the boys were working at farm labor and were capable of doing good work. Eighteen per cent. of the mentally defective children had exhibited tendencies toward wrong doing or social delinquency in some form. Eleven per cent. were illegitimate.

The conclusions of those in charge of the survey are that almshouses are not suitable places for the care of mentally defective persons; that the care of such persons in rural communities is neglected and little understood; that for many defective persons institutional care is necessary; that the state should make proper provision for such care and for suitable instruction for those children capable of profiting by it, and that public protection demands recognition of the relation between defective mentality and pauperism, degeneracy, crime, alcoholism and other social ills.

Medicolegal

Must Pay for Damage to Property by Pesthouse

(*Oklahoma City v. Vetter* (Okla.), 179 Pac. R. 473)

The Supreme Court of Oklahoma affirms a judgment in favor of the plaintiff for \$1,100 for damages sustained by her by the depreciation of the market value of real estate alleged to be suitable for residential and home purposes and damaged by the defendant by the erection on adjacent property of pesthouses or hospitals for the confinement and treatment of malignant, contagious and infectious diseases. The court says that the contention of the city was that, as the pesthouses were located under statutory authority, they could not be deemed a nuisance, and for that reason the plaintiff had no cause of action against the city. The question was whether the location of the pesthouses "damaged" the plaintiff's property in the sense in which the term is used in the provision of the state constitution that "private property shall not be taken or damaged for public use without just compensation." The conclusion of the court is that depreciation of the value of real property caused by establishing a hospital for contagious diseases, commonly known as a pesthouse, on adjacent land, although under statutory authority, constitutes a damaging of private property for public use, for which compensation must be made, within the meaning of the constitution. That the city, in erecting and operating a hospital for contagious diseases, was exercising a lawful governmental function did not warrant its exercise in violation of the constitutional guaranty to the citizen that private property should not be damaged for public use without just compensation.

Liability for "Felony of Abortion"

(*State v. Hawkins* (Mo.), 210 S. W. R. 4)

The Supreme Court of Missouri, Division No. 2, affirms a conviction of the defendant, a physician, under Section 4458 of the Revised Statutes of Missouri of 1909, of the "felony of abortion," for which he was sentenced to imprisonment in the county jail for sixty days and to pay a fine of \$800. The court says that the defendant corroborated the prosecutrix as to her visit to him, her statement to him of her pregnancy, his examination of her person to ascertain that fact, and his treatment of her; but he denied the use of any hard, pencil-shaped instrument on her person. He further testified that she was not pregnant, but that she was suffering when he treated her merely from delayed menstruation and a relaxed condition of the muscles of the womb and of the ligaments which support it. He

admitted the insertion into her parts of what he called "wool," but he said this was to support the womb, and, inferentially, not to stanch a flow of blood. To a physician called in by the prosecutrix on the second day after the operation, she said she disclosed only that she had suffered a miscarriage, whereupon he asked to be allowed to examine the fetus, and, being shown it, remarked, "That's it all right," as to which declaration the prosecutrix was corroborated by the testimony of her mother; but the physician, testifying for the defendant, denied that he found any evidence of a miscarriage, or of the prosecutrix's former pregnancy, and denied stating that when he examined the alleged fetus he admitted its identity as such. He said the prosecutrix was merely suffering from delayed menstruation. The court finds no error in the trial meet for reversal, and holds that, while the prosecutrix was impeached for that, her reputation for chastity was shown to be of the worst, and by divers contradictions, there was yet substantial proof, since the credibility of the witnesses was for the jury, and not for this court.

The provisions of Section 4458 apply not alone to physicians, but to all persons who may commit the offenses therein denounced. The only reference made in the section to physicians is that which makes it a defense if an abortion be committed by a duly licensed physician, or on the advice of a duly licensed physician, when such abortion is necessary to save the life of the woman, or of an unborn and quick child. It was not necessary to charge that the defendant was a licensed physician, if, as was done, it was charged that the abortion was not necessary to save the life of the woman, or the life of an unborn child, and that the defendant had not been advised by such a physician of such necessity for the act charged. If the pleader had charged that the defendant was a licensed physician, then it would not have been necessary either to charge or to prove that he did not act under the advice of a physician.

Section 4458 defines and denounces two crimes: (1) manslaughter in the second degree; and (2) the "felony of abortion." Both of these offenses are committed by identical means; they are differentiated solely by the result. If the woman die, or if, being with a quick child, such child die, the crime is manslaughter in the second degree. If the woman is not in fact pregnant, or if, though pregnant, the child or fetus is not quick, and the woman does not die, the crime is the so-called "felony of abortion." The count of the information on which the defendant was convicted followed the language of the statute, which was sufficient, presenting a sufficient charge of the "felony of abortion" in a case of pregnancy wherein the fetus had not quickened.

Liability of Husband for Medical Services

(*Bryant v. Lane (Ala.)*, 81 So. R. 364)

The Court of Appeals of Alabama says that this action was brought by plaintiff Lane, a physician, to recover for necessary medical attention rendered to the defendant's wife during childbirth and to his minor children, one of whom was the child of which the mother was delivered. It was found by the court that the defendant and his wife were temporarily apart, but were not divorced, and that the defendant had requested the plaintiff not to render any medical attention on his account; that the services rendered were necessary. There was no contention but that the defendant would be liable if the wife had not abandoned him without cause, and the court of appeals holds that the holding of the trial court in the finding of fact that the separation was temporary did not amount to an abandonment. It would be monstrous to lay down a rule that where a woman, in the nervous state incident to pregnancy, leaves her husband who is responsible for her condition, and goes temporarily to the sympathetic care of her mother, she will thus be deprived of the necessities of life due her by her husband, or be forced to accept them from some one not bound by law to contribute. This case was tried in the justice court, and the justice found for the plaintiff. It was tried anew in the circuit court, and the judge of that court, acting without a jury, found for the plaintiff; and, on the same state of facts, this court affirms his judgment.

Closing of Moving Picture Shows for Influenza

(*Alden v. State (Ariz.)*, 179 Pac. R. 646)

The Supreme Court of Arizona affirms an order that denied the application and dismissed the petition of Alden for a writ of habeas corpus, sought on the grounds that the local board of health was without constitutional authority to enact valid rules and regulations which would compel him to close his place of business. The court says that the petitioner was arrested on a warrant issued by a justice of the peace on a complaint charging the petitioner with the offense of wilfully, maliciously and unlawfully conducting and carrying on a moving picture show at Globe, in violation of the published rules and regulations of the local board of health, then in force to prevent the spread of Spanish influenza, a dangerous, contagious or infectious disease then raging in epidemic form in the city of Globe and Gila County. The particular rule that the petitioner was charged with having violated was as follows:

Rule 7. That it shall be unlawful for any person, persons, association, company or corporation to open, run, conduct, carry on, give or operate any pool room, theater, motion picture show, dance, or other amusement or room in the city of Globe or vicinity.

Rule 17 provided:

That these rules and regulations shall be in full force and effect immediately upon their being published and posted in accordance with law, and shall remain in full force and effect during the continuance of the present epidemic of Spanish influenza in the city of Globe and vicinity, and until the further order of the city health board.

Paragraph 4403, Revised Statutes of Arizona of 1913, declares that a violation of the rules, regulations and measures of the local health board, that have been published or of which the party violating has actual knowledge, is a misdemeanor and punishable as therein prescribed.

The questions of the power of the local health board to promulgate the particular rules and regulations here involved were considered by this court in *Globe School District No. 1, etc., v. Board of Health, etc.*, 179 Pac. R. 55, and reported in the *Medicolegal Department of THE JOURNAL*, June 21, 1919, under the heading: "Board of Health Closing Schools for Influenza." The supreme court concluded in that case that the rules and regulations adopted were within the power of the local board and were enforceable during the period of the existence of the epidemic, as a reasonable measure to prevent the spread of the disease. The court will not again enter into a discussion of the questions there discussed and decided.

It appeared in the present case that, at the time the petitioner was alleged to have opened his moving picture show, the Spanish influenza was raging in epidemic form; the facts in this respect appeared in the *Globe School District No. 1* case, and may not be repeated. In the circumstances admittedly existing, the petitioner was subject to prosecution and therefore arrest, if, as a fact, he wilfully and knowingly violated the health rules by opening his said moving picture show and place of entertainment at that particular period of time. Consequently his arrest was lawful, and the judgment of the lower court is affirmed.

Neuropsychiatry in Army Camps.—During the months from May to September, 1918, inclusive, 54,000 recruits were examined at Camp Upton, N. Y. Of this number 1,050, or 2 per cent., were rejected for nervous and mental disorders. At Camp Gordon in four months, July to October, inclusive, 58,850 men gave a rejection of 1,225, or 2.8 per cent., for similar diseases and conditions. At Camp Upton drug addicts constituted 17 per cent. of the rejections for mental disease, while at Camp Gordon they made up 3.27 per cent. of such rejections. A survey of 100 drug addicts gave them a mental age rating of twelve years. Large numbers of epileptics entered camps, later to be discharged when their disabilities became apparent. Probably about 3.5 per cent. of 1,050 rejections were because of this disease. Thirty per cent. of rejections for nervous and mental disabilities were for mental deficiency, about 0.6 per cent. of all cases examined. Manic-depressive psychoses were present in very small numbers. The alcoholic psychoses were not numerous. Neurosyphilis contributed many cases for rejection, taken in the aggregate. In one draft of 800, these cases amounted to 0.7 per cent. of men examined. Emotional instability, inadequate personality, and sexual psychopathics were classified.

 Sensory Changes in Peripheral Nerve Injuries. L. E. Grunberg, New York.—p. 338.

Peripheral Nerve Injuries Result of Gunshot Wounds.—On the basis of neurologic examinations, supported by subsequent operative findings, Spear and Babcock are of the opinion that from 60 to 75 per cent. of the patients with nerve injuries seen by them at Base Hospital No. 6 would not recover lost function without operative interference. The operative cases have not been under observation a sufficient length of time to arrive at a more than tentative conclusion as to ultimate outcome. The neurolysis and bersage cases have shown a considerable number of improvements, but measurable, objective improvement in the suture cases has been very limited.

Bulbar Paralysis. A case is cited by Hassin which he believes demonstrates the identity of amyotrophic lateral sclerosis and chronic bulbar paralysis.

Psychoses of Influenza. McMeninger aims to illustrate the forms of psychoses associated with influenza by the presentation of representative cases. Influenza apparently acts on the brain in three ways: to create psychoses, to precipitate psychoses in predisposed subjects, and to augment or alter their form where already existent.

 Will the War Influence the Practice of Medicine, as a Business? J. C. King, Banning, Calif.—p. 346.

Epidemic of Filaria Onchocerca.—There has been discovered in the Republic of Guatemala, by Dr. Rodolfo Robles, a new disease of parasitic origin, hitherto unknown in the American continent, commonly called erysipelas of the coast; produced by infection by a parasite—filaria onchocerca. The clinical history of this affection is described in detail by Fee.

Rapid Administration of Digitalis in Cardiac Decompensation.—In the wards of the medical clinic at the Stanford medical school, in selected cases, from 20 to 28 c.c. of a standardized tincture of digitalis are given within from twenty-four to thirty-six hours in treating this affection. Of this amount from 12 to 16 c.c. are administered on the afternoon of admission, and 4 c.c. after each of the three meals on the following day. The administration is then stopped and is not resumed until clinical or electrocardiographic observation indicate a decline in the effect of the drug. This usually occurs after from three to five days. The usual dose of from 1 to 2 c.c., three times a day, is then given. In favorable cases a striking improvement may be obtained within twenty-four hours, by the rapid oral administration of digitalis in large doses. This improvement is shown by a slowing of the pulse rate, by a reduction of difference between apex and radial rates in auricular fibrillation, by the removal of edema (a sudden fall in body weight) and by the relief of symptoms. Serious toxic effects were not observed.

Camphor in Pneumonia.—In 100 cases of lobar pneumonia Gundrum injected 15 c.c. of a 20 per cent. solution of camphor in olive oil, twice daily, for the purpose of determining its value. He found that it had no demonstrable effect on the circulation or on the course of the disease. The mortality from lobar pneumonia was 21 per cent.; bronchopneumonia, 41 per cent.; untreated pneumonia, 58 per cent.

Canadian Journal of Mental Hygiene, Toronto

July, 1919, 1, No. 2

- *State Programs for Care of Mentally Defective. W. F. Fernhall, Mass.—p. 119.

- Mental Deficiency in Relation to Venereal Disease. A. F. Tredgold.—p. 188.

State Programs for Mentally Defective.—The program which Fernald believes to be a feasible one includes the mental examination of backward schoolchildren, the mental clinic, the traveling clinic, the special class, directed training of individual defectives in country schools, instruction of parents of defective children, aftercare of special class pupils, special training of teachers in normal schools, census and registration of the feeble-minded, extra-institutional supervision of all uncared for defectives in the community, selection of the defectives who most need segregation for institutional care, for such care, increased institutional facilities, parole for suitable institutionally trained defectives, permanent segregation for those who need segregation, mental examinations of persons accused of crime and of all inmates of penal institutions, and long continued segregation of defective delinquents in special institutions.

Supervision of Feeble-minded.—Taft urges that a system of community supervision of the feeble-minded in connection with the school system is absolutely necessary for a term of years: (1) in order to deal with the problem of control and prevention of feeble-mindedness while segregation and sterilization are as yet inadequate; (2) in order to get facts regarding the feeble-minded who can and those who cannot be adapted to life outside an institution; (3) in order to determine whether there is anything better than the colony plan for utilizing the labor of the feeble-minded; (4) in order to educate the community to an understanding of the problem; (5) in order to justify the existence of special or ungraded classes and render them really useful; (6) in order to provide an opportunity for the study of the individual cases not *a priori* delinquent or belonging to the group obviously requiring segregation.

- *Experiments with *B. Influenzae*; Its Toxin and Antitoxin. A. Preliminary Report. N. S. Ferry and E. M. Houghton, Detroit.—p. 233.

Bactericidal Action of Blood of Rabbits.—The most general conclusion, and the most important one, drawn by Heist and Solis-Cohen from their work on the bactericidal activity of whole blood *in vitro* is that such blood, before it coagulates, possesses bactericidal properties which can be investigated and measured with considerable accuracy, properties which do not become apparent when blood serum alone is examined. The production, by suitable inoculations, of specific bactericidal activity in the blood of rabbits, for pneumococci of one type, is accompanied by the production of slight bactericidal activity for other types. A bacterin prepared from

pneumococci washed from the peritoneal cavity of a rabbit dying of pneumococcal infection is more powerful as an immunizing agent for rabbits than one prepared from pneumococci grown on artificial culture mediums.

Rôle of Bacillus Influenzae in Clinical Influenza.—The experimental evidence obtained by Hantmon and Hannum showed that *B. influenzae* is capable of producing a toxic substance; that this substance when introduced into the circulation, produces congestion of the respiratory tract with hemorrhages into the alveoli. Certain conditions of symbiotic growth intensify the liberation of the toxin. As an effect of the action of the poison the lungs show a predisposition to invasion by various organisms, with the production of secondary lesions. Live bacilli introduced at a remote point probably affect the lungs through the action of a liberated toxin. There is nothing in the serologic evidence to preclude the consideration of this organism as an important factor in the causation of clinical influenza.

Bacteriology and Selective Action of *B. Influenzae*.—Roos says that *B. Influenzae* can be found in every case of true clinical influenza. To isolate this organism, which is most abundant in the earlier stages of the disease, it is necessary to exercise care on obtaining a suitable specimen, and since growth requirements of this organism are quite rigid, special selective culture media, such as those suggested by Avery and also by Fleming, carefully prepared and adjusted to reaction are essential for successful work. The various strains of *B. influenzae* apparently do not differ in kind. The toxic substances of *B. influenzae* show a marked action on the bronchopulmonary tract, thereby predisposing these organs to extensive invasion by the organism itself or to secondary infections. No marked increase in virulence of *B. influenzae* has been obtained by passages through laboratory animals. No bacteremia is produced by *B. influenzae* in laboratory animals by a dose approximating a minimum lethal dose regardless of the mode of injection chosen. The pathologic lesions in the rabbit, gross and microscopic, in many respects resemble those of influenza in human beings as observed during the past pandemic. The injection of *B. influenzae* into the rabbit intravenously results in a rapid and marked decrease in the polymorphonuclear cells.

Studies in Protein Intoxication.—The animals used by Boughton in his experimental work were sensitized by three doses of egg white; one subcutaneous, one intraperitoneal and one intravenous, at intervals of from one to three days. The animals were given the first toxic injection about three weeks after the last sensitizing injection. The later doses were given at varying intervals, and the size of the dose was gradually increased with the purpose of giving each animal as many anaphylactic shocks as possible, without killing the animal, on the one hand, and, on the other hand, without producing the refractory stage. Repeated injections produced pathologic lesions of the kidney, heart, liver, spleen and lung. These lesions consist of degeneration and necrosis of the parenchymatous cells, round cell infiltration, fibrosis and edema and thickening of the walls of the smaller arteries. The parenchymatous lesions were present in practically all the kidneys, but only a few hearts and livers. The infiltration was present in nearly all the kidneys, hearts and livers, and was most prominent in the kidneys and least prominent in the hearts. The vascular lesions were most frequent in the spleen, lung and heart, but were not severe in any case.

***B. Influenzae*: Its Toxin and Antitoxin.**—Ferry and Houghton point out that irrespective of the etiologic relationship of the Pfeiffer bacillus to influenza it is an interesting fact to know that a soluble toxin can be produced which will stimulate the formation of an antitoxin. It is, also, of great scientific importance to know that this antitoxin cannot only neutralize the toxin *in vivo* as well as *in vitro*, but it can also protect against bacterial infection of the guinea-pig with *B. influenzae*. Two outstanding facts are emphasized; namely, the extreme congestion following an injection of guinea-pigs with *B. influenzae*, and the profound prostration in rabbits, due to a toxemia, following the injection of the toxin, which very closely simulates the early stages of influenza in the human subject.

Fermentation Reactions of Certain Streptococci.—It is claimed by Kendall et al. that the classification of bacteria, including the streptococci, therefore, on the basis of fermentation reactions makes it possible to separate them into convenient and distinct groups which have divisional value. There is no clearly discernible relationship, however, between cultural grouping based on carbohydrate and pathogenesis.

Is Hemoglobin Antigenic?—Hemoglobin was prepared by Schmidt and Bennett by three methods, one by crystallization from ammonium sulphate as described by Schulz, and the other two by precipitation as oxyhemoglobin (with and without addition of alcohol) at low temperatures and resolution by reduction. Each of the three preparations was recrystallized a number of times. Rabbits were immunized with each of the above preparations and both fixation and precipitin tests carried out. These were negative. In the serum of these rabbits no sensitizer was found, which, in the presence of alexin, cause a hemolysis of dog cells. Agglutinins were likewise not produced. Hemoglobin failed to sensitize guinea-pigs for the anaphylaxis reaction. The authors believe that the conclusion that hemoglobin is nonantigenic seems warranted. Doses of hemoglobin very much larger than the amount of globin which will cause toxic symptoms were injected both intravenously and intraperitoneally into guinea-pigs and toxic symptoms were not shown. Combination of toxic globin with hematin as occurs in hemoglobin renders it nontoxic, but does not, as in the instance when globin is combined with casein, give, when rabbits are immunized, antibodies for itself.

Pathogenic Cocci in Tuberculous Sputum.—Corper and Enright studied the sputum in thirty-seven cases of pulmonary tuberculosis by injecting it into mice (intraperitoneally) and culturing and typing directly from the peritoneal fluid, and then comparing these results with those previously obtained by cultural methods. The organisms from the sputum of open cases of pulmonary tuberculosis obtained by intraperitoneal injection of mice were mainly pneumococci of types III and IV, and a few of type II, the types which are considered saprophytic by Pritchett and Stillman in contradistinction to the pneumococcus I and certain strains of type II. A few hemolytic streptococci and *Streptococcus viridans* were also found in the sputum. As a whole, the organisms

found in the sputum from open cases of pulmonary tuberculosis by mouse inoculation differed little from those found in the saliva of the same cases and in the sputum and saliva of normal individuals. These results are corroborative of previous results by direct culture methods from which it was concluded that the organisms in the sputum in pulmonary tuberculosis ordinarily play an insignificant part in the pathogenesis of this disease. As far as the presence of these organisms in the lung are concerned, the authors claim that they are to be considered more as would their presence in any nontuberculous disease, and as indicating a condition of lowered local resistance which makes possible a saprophytic residence of such bacteria. Just why the so-called parasitic types are not found remains to be discovered, as does also the infrequent occurrence of pneumococcus pneumonia in pulmonary tuberculosis.

Diphtheria Bacilli in Empyema Wounds.—An organism corresponding morphologically to the diphtheria bacillus was found by Simmons and Bigelow in a culture from a healing postoperative empyema wound. Cases showing this organism increased in number until a short time later sixty of the empyema wounds were infected. Of the strains isolated, 17.8 per cent. were virulent for guinea-pigs, and all of these strains failed to produce acid when grown in saccharose broth cultures for eight days. The degree of virulence among saccharose negative strains was variable. The morphologic characteristics presented by both virulent and avirulent strains were the same. All cultures contained a mixture of Wesbrook's type A, C and D, with the subtypes. There was no evidence of the development of specific agglutinins, precipitins or complement fixing substances for diphtheria bacilli (virulent or avirulent) in the serum of the infected individual. Apparently there was no invasion of the blood stream by the diphtheria bacilli in the wounds. All methods of treatment tried proved unsatisfactory, due probably to the growth of bacilli deep in the wound granulations. As a rule, the carrier state continued until complete healing of the wounds had taken place.

Thorium X and Anaphylaxis.—The object of the experiments made by Corper was to obtain a method applicable to the study of one of the problems in tuberculosis—that of allergy. He found that thorium X, given in about one and one half the lethal amount seven days before or coincident with the primary injection of egg white, normal horse serum or milk proteins, or seven days before or with the second injection of these proteins, had no appreciable effect on the severity of the anaphylactic symptoms in guinea-pigs or reinjection of protein sixteen to eighteen days after the primary injection. Likewise, the repeated administration of smaller doses of thorium X, sufficient to maintain a leukopenia as low as 2000 leukocytes per cubic millimeter throughout the entire interval of sixteen to eighteen days between the first and second injections, or very small repeated injections not appreciably affecting the number of peripheral leukocytes, had just as little effect on the severity of the anaphylactic symptoms. There was no direct relation noted between the anaphylactic symptoms and the leukocyte counts as affected by thorium X. In the larger doses the effect observed seemed to be due to the combined action of two toxic substances: the thorium X, a chronic poison, and the anaphylatoxin, an acute poison.

Rapid Determination of Hydrogen Ion Concentrations.—A new apparatus for determining the dilution of hydrogen ion in bacterial cultures and other fluids is described by Jones. As compared with the colorimetric method, the apparatus here described has wider application, is more accurate, less cumbersome and only slightly less rapid. The hydrogen electrode vessel described was designed with two objects, chiefly, in mind: (1) to provide a vessel accurate at least to 0.01 pH and (2) to provide a vessel giving rapid saturation with hydrogen gas, and yet one which is easily constructed. A rapid and labor saving technique combining the indicator, and the gas-chamber methods is described, which obviates the difficult task of preparing standard solution for the former methods, and of making needless repetitions by the latter.

- *Iodin: Effect on Fibrous Nodules. T. Sollmann, Cleveland.—p. 495.

Effect of Morphine on Blood of Gassed Dogs.—Hjort and Taylor found that morphine sulphate administered subcutaneously to normal dogs in doses of 10 mg. per kilogram causes an increase in the alkali reserve which is maintained at a high level for many hours. Concentrations of approximately 0.08 per cent. by volume of chlorin gas produce within from two to seven hours a rapidly advancing condition of acidosis. This may be preceded by a temporary increase in the alkali reserve. In dogs gassed with this concentration of chlorin, morphine, in the 10 mg. per kilogram doses, may temporarily prolong the maintenance of a high alkali reserve level; these doses, however, exert, if anything an unfavorable influence on the ultimate outcome. An external temperature of 33 C. appears to affect unfavorably the course of the alkali reserve in gassed dogs that had been treated with morphine previously.

Action of Epinephrine on Spleen.—According to Hartman and Lang dilatation of the spleen is caused by the action of epinephrine on the twelfth and thirteenth dorsal root ganglia, the scimitar ganglion or on some terminal structure in the spleen itself. Constriction can result from the response of a mechanism in the dorsal root ganglia or from a structure in the spleen.

Comparative Activity of Local Anesthetics.—The efficiency of the difficultly soluble local anesthetics for mucous membranes, according to Sollmann may be demonstrated on the cornea of rabbits or on the gums of human subjects. An approximate estimate of their relative efficiency may be obtained by comparing dilutions made with talcum powder. On the cornea, anesthesia, cycloform, orthoform-new and propaesin appear to be practically equivalent. They are certainly effective in concentrations of 10 per cent.; uncertain at 5 per cent. and practically ineffective at 2.5 per cent. The anesthesia persists for from ten to fifteen minutes with 10 per cent.; from fifteen to thirty minutes with 25 to 100 per cent. On the gums a greater variation was noted. The minimum concentrations giving almost complete anesthesia were as follows: Cycloform, less than 2.5 per cent.; anesthesia, from 2.5 to 5.0 per cent.; propaesin, from 5.0 to 10.0 per cent.; orthoform-new, from 10.0 to 25.0 per cent.

Pharmacology of Local Anesthetics.—The more important literature of acute intoxication in man from the local anesthetics is reviewed by Eggleston and Hatcher and cases are cited to show the close similarity between the symptoms produced in man and in the lower animals, especially the cat. The phenomena of acute intoxication in the cat, following the intravenous injection of the local anesthetics, are described, and the similarity of the phenomena produced by different members of the group is emphasized. The maximum toxicity for each of the members of the series has been determined by rapid intravenous injection in the cat, and the relative toxicities of the several drugs are represented graphically. The several different local anesthetics are shown to be mutually and quantitatively synergistic, so far as their fatal actions are concerned. The capacity of the cat to withstand the intravenous injection of several times the fatal vein dose of any of the local anesthetics, except cocaine and holocain, has been shown by repeated injections of large doses, or the continuous injection of relatively dilute solutions. The toxicity of the local anesthetics for the cat, after subcutaneous injection, has been shown to depend on

the ratio between the rate of absorption and that of elimination, and the local anesthetics can be divided into two classes with reference to that ratio. Five, or more than five, times the minimal fatal vein dose of alypin, aepthesin, beta-eucain, nirvanin, procain, stovain and tropacocain can be injected subcutaneously in the cat without causing death, while four, or less than four, times the fatal vein doses of cocaine and holocain similarly injected prove fatal. The simultaneous subcutaneous injection of epinephrine with the local anesthetics materially reduces the toxicity of the latter by delay in the rate of their absorption, but this reduction is much less marked in the cases of cocaine and holocain than with the other members of the series, and is referable to their much slower "essential" elimination. The absorption of several of the local anesthetics from the mucous membranes of the nose and pharynx of the cat has been shown to be no more rapid than from the subcutaneous tissues, and the urethra, bladder and vagina resist the absorption of these drugs to a great extent. The elimination of the local anesthetics in the cat has been demonstrated to be due to their rapid destruction by the liver, and this takes place in the excised, perfused organ as well as in the liver of the intact animal. All of the local anesthetics have been shown to be synergistic with epinephrine on the blood pressure in a manner analogous to cocaine. The employment of artificial respiration, combined with stimulation of the heart by the intravenous injection of epinephrine is capable of saving cats from death following the intravenous injection of as much as twice the average fatal dose of the local anesthetics. Stimulation of the heart by the previous injection of ouabain permits the cat to recover from intravenous injections of nearly twice the average fatal dose of the local anesthetics, when the temporary paralysis of the respiratory center is combated by the use of artificial respiration. The success of the last two measures depends on the rapid destruction of the local anesthetics by the liver.

Effect of Iodin on Fibrous Nodules.—Intradermal fibrous nodules, produced by intracutaneous injections, were treated by Sollmann with local applications of iodine to test its absorptive efficiency. Very definite effects were obtained by daily applications, continued at least eight days, and pushed to considerable irritation of the skin. Treatment over shorter periods was inefficient, even when the dosage and the irritation were greater.

- Trench Fever.** R. D. Rudolf.—p. 414.

Whispered Voice Sound.—At the base hospital, Camp Pike, Ark., it was noticed that bronchophony was a constant accompaniment of every case and it was felt that this physical sign was merely an expression of transmission of sound through the bronchi to the chest wall, due to increased lung infiltration. These sounds coming to the ear in exaggerated form, led to the thought that the whispered voice sound would be as evident, and it was found that small areas of patchy consolidation which were not demonstrable by percussion and over which bronchial breathing was not determinable, were brought out and could be defined sharply by this method. Carrying this idea further, it was found that the entire lung surfaces could be examined systematically in a short space of time with the ordinary bell of a Bowditch stethoscope, by going from ring to ring as marked on the chest wall and by this method the areas of consolidation could be outlined sharply and nicely differentiated from the uninvolved area immediately adjoining it. The point or place of the whispered voice sound Lissner says is not new in physical diag-

nosis but its application to the diagnosis of early pneumonic consolidation is a new departure and gives to this particular sign an added value.

- Treatment of Purulent Pleural Effusions. T. Tuffier, Paris, France.—p. 464.

Pulmonary Suppuration.—Up to 1919, seventy patients have been operated on at the Mayo Clinic for pulmonary suppuration. The combined mortality from all causes, including bronchiectasis, was 33.3 per cent. Hedblom's study is concerned chiefly with fifty-four cases in which operation had been done since 1910. There are included also two cases that progressed to a spontaneous cure and twenty-four necropsy cases. In seventeen of the twenty-four necropsy cases abscess occurred as a post-operative complication; in sixteen the abscesses were multiple. In seven instances the patients were either moribund on admission or the condition was not recognized clinically. Hedblom is convinced that primary suppuration of the lung is rare. Suppuration occurs on a preceding inflammatory basis, or the infection is carried to the lung tissue through the bronchus, the blood stream, or by direct extension. A persistent productive cough is the most characteristic symptom. The sputum is usually purulent, and often foul. Other clinical features of suppuration are present in varying frequency and degree. Localized dullness to percussion and a circumscribed roentgen-ray shadow are the most constant physical findings. Pulmonary suppuration is probably frequently mistaken for phthisis. In 33 per cent. of the cases reported by Hedblom symptoms were suggestive of tuberculosis. The treatment of localized suppuration is early free drainage. Prolonged expectant treatment or inefficient drainage greatly increases post-operative morbidity and mortality. Local and regional anesthesia is safe and in most cases very satisfactory. The abscess should be drained only through the adherent pleura or after the pleural cavity has been walled off by suture of the lung to the parietal pleura. A two-stage operation allowing a few days for adhesions to form around the suture line Hedblom says is probably the best safeguard against empyema, which is a frequent and the most dangerous complication.

Tuberculin Therapy in Children.—Newton reports seven cases, nearly all of which showed very perceptible improvement from comparatively small, or very small doses of tuberculin. Of four cases of peritoneal tuberculosis, three patients were brought under treatment within a few weeks of the appearance of the ascites and the improvement was prompt and gratifying; while one patient gave much more trouble and took much longer to recover, and this in spite of the fact that he had been removed from an unfavorable environment in the slums of a great city to a markedly salubrious one in the country. Newton also claims to have achieved excellent results in the tuberculin treatment of three cases of pulmonary tuberculosis that had come under treatment within a few months of the beginning of active pulmonary lesions, while cases of longer standing, although improving for a time, under tuberculin, have failed to show a permanent arrest. Newton emphasizes that, generally speaking, tuberculin must be used early if it is to be of permanent benefit.

Blood Picture in Exophthalmic Goiter.—The claim made by some observers that anemia of the chlorotic type is a characteristic of exophthalmic goiter is not borne out by Plummer's findings based on an examination of the blood of 578 patients. An anemia, when present, is neither the result of, nor necessarily coincident with, hyperthyroidism, but is due to secondary changes. The real status in regard to the number of leukocytes in patients with exophthalmic goiter is that there is a wider variation, probably dependent on the neutrophils, than among normal counts, and while there are more counts showing a decrease in leukocytes there is an equally large number showing a slight increase. Plummer has not been able to demonstrate that a leukopenia is more frequently present in the early stages of the disease. In the majority of the cases there is a relative and absolute mononucleosis; and when a leukopenia is present the decrease takes place at the expense of the neutrophils; but the converse is true to a lesser degree. The eosinophils show some variation, but the total averages give no increase. In the mortality statistics of the Mayo Clinic the relative lymphocyte count is a few points under the average for the entire series but it is not sufficient to be of value in prognosis. The differential count is of limited value in diagnosis. Except for a polymorphonuclear leukocytosis immediately following operation, and during tonsillitis and other acute infections, Plummer has been unable to determine any factor which influences the characteristic blood picture.

Abscess of Lung: Treatment.—In sixteen cases of lung abscess treated in the Mayo Clinic the apparent etiologic factors were as follows: pneumonia (postoperative), four cases; teeth extraction, three cases; tonsillectomy (operation elsewhere under general anesthesia), two cases; gastroenterostomy for ulcer, grip and trauma (followed by pneumonia), one case each; questionable, four cases. All the patients were operated on regardless of the fact that several were desperately ill and, therefore, were very poor surgical risks. Three patients died; a mortality of 18.7 per cent. All of the remaining thirteen are improved. In three of these the operation is too recent to classify as to the permanent result. Two have bronchial fistulas that will probably require plastic operation. Seven are cured in the sense that there is no sinus and they have no symptoms referable to the pulmonary lesion. The treatment consisted of drainage.

Therapeutic Effects of Overfeeding in Pernicious Anemia.—Three cases of pernicious anemia have been studied by Peppard with reference to the effect of forced feeding. In two cases, possibly in all of them, a positive nitrogen balance was secured without difficulty. During the gain in weight symptomatic improvement took place and there was a distinct betterment in the blood picture. A diet allowing from sixty to sixty-five calories per kilogram (approximately double the minimum requirement) is recommended, this to be given in proportions of protein, 16 per cent.; fat, 42 per cent., and carbohydrates, 42 per cent.

Effects of a Scurbutic Diet on Suprarenals. A pronounced reduction in the amount of epinephrin in the suprarenal glands was found by McCarrison to result in guinea-pigs from a scurbutic dietary of crushed oats and autoclaved milk.

Sudden Detachment of Aortic Intima. The Walkers cite the case of a man, 65 years of age, apparently in good health, who fell down suddenly and nearly died; he recovered somewhat, and complained of intense substernal pain and of pain and paresis of the left leg. About thirty-eight hours later he died suddenly. The postmortem examination disclosed the greater part of the aortic intima lying free in the lumen. The aorta was extensively atheromatous. The mechanism of the process, and of the so-called dissecting aneurysm, is discussed. It is maintained that in the absence of bulging of the outer coats, static considerations alone do not provide an adequate explanation, but that the motion of the blood is a significant factor.

Leucine: Its Occurrence and Significance in the Urine. R. W. Allen—p. 238.

Viruses of Trench Fever and Influenza.—Arkwright has been unable to confirm any of the experimental results reported by other investigators on the bacteriology of trench fever and influenza. He has been unable to distinguish macroscopically or microscopically between tubes inoculated with trench fever or influenza virus and control tubes at any period between their first inoculation and three weeks later, or over a longer period. The culture tubes showing a considerable amount of deposit or turbidity of the serum broth have, when examined, always proved to be contaminated by bacteria, as shown by subculture and microscopic examination. Two tubes selected by Wilson from his own culture after macroscopic and microscopic examination as good examples of growth of (a) trench fever and (b) influenza virus proved to be grossly contaminated by large staphylococci and appeared to Arkwright to contain no other organisms. Of three films shown as typical of the trench fever virus from different cases of trench fever and showing organisms of similar morphology, two appeared to be undoubtedly films of a diphtheroid bacillus irregularly stained, the third film also contained diphtheroid bacilli and in addition large numbers of a small bacillus of different appearance. Other tubes regarded by Wilson after macroscopic and microscopic examination as examples of cultures of trench fever, which did not contain ordinary bacteria, showed in Arkwright's opinion only appearances which were also found in control tubes. The forms claimed by Bradford, Bashford and Wilson as the micro-organisms of trench fever and influenza appear to Arkwright to be of two kinds: (a) Bacteria of the size of a staphylococcus or a diphtheroid bacillus, but only partially stained (polar or central staining). (b) Smaller or larger granules of precipitated protein which stain much more feebly than (a) and are also found in control tubes. Some of Wilson's films appear to contain both and some only the latter forms. In Arkwright's opinion Wilson has been misled by the appearances in films of bacteria feebly stained with methylene blue, in which only partial, for example, polar, staining is seen, and in the case of cultures from which bacteria have been absent he has been deceived by the diplococcus like or dumbbell shaped forms often seen in protein precipitates, and has regarded these granules as organisms. That Bradford, Bashford and Wilson should have been so misled in their researches appears to be due to the following causes: 1. The conditions under which they worked in isolation from other bacteriologists, conditions which would scarcely have obtained in times of peace. 2. A tendency to place undue reliance on the efficacy of filters and glycerin for removing or killing bacteria. 3. A misconception as to the size of the bodies seen in their films. 4. Inadequate staining. 5. Insufficient use of subculture on to ordinary mediums as a test for bacterial contamination.

*Perithionia Stimulating Pancreatic Cyst. R. E. Smith—p. 270.
Avoidance of Relapse in Gonorrhoea by Electrolysis. C. Ross—p. 270.

Cases of Rapidly Fatal Spinal Caries. Each of the three men whose illness is reported on by Collins appeared robust and gave a good previous health report, with the exception that one patient gave a history of pains in his back. The first patient was of a quite exceptionally fine physique, and said he had always enjoyed excellent health. The illness of the first patient lasted six days, that of the second fifteen days, that of the third nine days. The onset in each case was swift and without warning. The first patient, to his surprise, found himself unable to walk to the medical hut; the other two patients found one day, when in hospital, that

they had become powerless in their legs. The first patient had six months' service, the second one year and five months, and the third two years and three months. There was no history of trauma in any of these cases. The patients died. A necropsy report is submitted in each case.

Relative Value of Intravenous and Intramuscular Injection of Arspenamin.—On the basis of clinical results obtained in a large number of cases, Leonard favors the intramuscular method of administering arspenamin, although good results were also obtained from the intravenous method. He emphasizes the importance of early treatment, and that quackery—advertised "remedies" and counter prescribing—should be dealt with more rigorously in order to prevent serious delay in commencing proper treatment.

Pterithelioma Simulating Pancreatic Cyst.—In Smith's case the pseudocyst of the pancreas so closely simulated a true cyst of that organ that it was only at the necropsy and by tissue section that the true pathologic condition was determined. The growth had no definite capsule, except some feeble granulation tissue. The mass and its contents showed numerous blood spaces lined by large malignant cells radially arranged and spreading in solid masses from the blood spaces. There was much degeneration at the points distant from the spaces. The malignant cells were large with deeply staining cytoplasm; nuclei large, pale, and showing an active mitosis. The growth was a pterithelioma or an encephaloid carcinoma with degeneration at the points remote from the blood spaces.

Editorial Notices

Fractures of Femur. Driberg points out that by the use of any one of the methods described by him a perfect result can be obtained in the vast majority of fractured femurs, but success depends, in large part, on the exercise of constant care and attention to detail. The adjustment of the sling, the maintenance of the extension, the movements of the knee joint, the correct suspension with slight eversion of the limb, the prevention of foot drop, massage, and the upkeep of general health and nutrition of the patient—each of these plays its allotted part in the attainment of perfection; and if any one is neglected the seeker after perfection is apt to be disappointed.

Antiscorbutic and Growth Promoting Value of Canned Vegetables. Previous investigators have shown that canned vegetables suffer considerable deterioration in antiscorbutic value owing to the high temperature to which they are exposed in the process of preparation. Campbell and Chick did some experimental work to obtain an accurate estimate

of what that loss might be. Cabbage and green (runner) bean pods were selected as suitable vegetables for the experiment. The experiments consisted essentially in estimating and comparing the minimal amounts of these vegetables, (a) when raw, and (b) after canning, which must be added daily to a basal scurvy producing diet in order to protect young guinea-pigs from scurvy over a period of three months. It was learned that in the process of canning vegetables the greater part of the original antiscorbutic value of the raw vegetable is destroyed. In the case of runner bean pods the loss is estimated at about 90 per cent. of the original value; in the case of cabbage at about 70 per cent. of the original value. This loss is primarily due to the destruction of antiscorbutic material occurring during the heating involved in the process of canning. A further loss may be expected to take place during the period of storage. This canned cabbage was examined two weeks after preparation and the canned beans three months afterward. In the case of green leaf vegetables which possess, in addition to the antiscorbutic vitamin, the "fat-soluble" growth promoting accessory factor, the latter substance is also lacking in the canned material unless the liquor be also taken. Therefore, the value of canned vegetables as regards antiscorbutic and growth promoting properties must be regarded as negligible.

Antiscorbutic Value of Some Indian Dried Fruits.—Chick and her associates state that dry tamarind, cocum and mango possess a definite but small antiscorbutic value. This value is greatly inferior to that of raw cabbages, swedes, germinated pulses, orange juice, lemon juice, but equal or superior to that of carrots, beet roots, cooked potatoes, raw meat juice—reckoned weight for weight in the natural condition.

Antiscorbutic Properties of Fresh, Heated and Dried Cow's Milk.—The antiscorbutic value of cow's milk, fresh, heated and dried, was determined by Barnes and Hume by means of quantitative nutritional experiments with guinea-pigs and monkeys. Cow's milk, even when fresh, was found to be a foodstuff comparatively poor in antiscorbutic properties, and large daily rations, 100 to 150 c.c. daily for guinea-pigs and 125 to 175 c.c. daily for monkeys, were needed to protect these animals from scurvy, when on a diet otherwise devoid of antiscorbutic material. Dried milk was found inferior to raw milk in this respect. Even with material of quite recent manufacture the authors were unable to protect guinea-pigs from scurvy with any amounts that it was found possible to administer. In case of monkeys the minimum protective dose was found to be approximately from 20 to 300 c.c. daily; in other words, about half the original antiscorbutic value of the fresh milk had been destroyed in the process of drying. "Scalded" milk was found distinctly superior to dried milk. These facts form a strong argument for the desirability of adding an extra antiscorbutic to the diet of infants nourished on dried milk. The most suitable substances for this purpose are raw orange juice, raw swede juice, or juice of tomatoes, raw or canned. Grape juice and carrot juice are also useful but less valuable, as, being inferior in potency, correspondingly large doses are required. Potatoes, cooked and mashed, can be employed in cases where starchy foods are not considered unsuitable. Some evidence was obtained showing that winter milk is inferior to summer milk in antiscorbutic properties, corresponding to the differences in the cow's diet at these different seasons. In this connection the suggestion is made that the value of winter milk in this respect might be raised if swedes were employed for winter feedings in place of mangolds, where possible. No significant difference was detected in the growth promoting properties of raw and dried milk, respectively, and this was true with both guinea-pigs and monkeys. In both cases growth declined with the onset of scurvy symptoms, but until this occurred the growth made on diets containing dried milk was equal to that obtaining when equal rations of fresh milk were substituted.

Immunized Skin Grafts.—The method which Yates says was used by German surgeons during the war consists of placing the dressing, which has been in contact with the surface of the wound it is intended to treat and which is therefore soaked in the discharges of the wounds, on an area

of skin suitable for obtaining grafts by the Thiersch method and allowing this dressing to remain in position for twenty-four hours, after which it is replaced by another dressing removed from contact with the wound. Applied with these precautions, the skin with which the wound discharges were brought in contact, was found to reddens and to show on the third day of the application a slight prominence of the papillae. It was necessary to watch the skin carefully at this point in the treatment as it is of considerable importance to guard against the occurrence of a violent reaction. When the skin showed a marked elevation of the papillae and slight reddening, the treatment of the area was stopped for a day, but in most cases it was possible to treat the skin in this way for a period of seven days, after which the graft was ready for removal.

Cryptopodia.—Bousfield's patient, a woman, 44 years of age, first noticed enlargement of the feet at the age of 15, coming on during the day and disappearing during sleep. She appears to have continued in service, though with increasing difficulty, until her twenty-fifth year, when she was attacked by rheumatoid arthritis, which left her hands crippled, and since then the feet have got steadily worse, so that for ten years she has not been able to walk. The suggestion is that of elephantiasis, but the fact that the toes are not involved in the tumor, and the great separation of the hair follicles, indicating distention, not hypertrophy, together with the translucence of the tumors, negative the idea of that disease. The swelling extends from about 3 inches below the knees, and involves the whole of both legs and the dorsum of the feet, but stops absolutely short at the margins of the soles, or rather folds over about half an inch higher all around. Around each ankle there is a well marked collar, with protuberances not coinciding with any anatomic structures. The skin pits deeply on pressure, but there is neither pain nor tenderness. Heart, lungs and kidneys are sound. A blood count showed 32 per cent polymorphonuclear leukocytes, 17 per cent. transitionals, 51 per cent. small lymphocytes, but neither large mononuclears nor eosinophils. The red cells were very irregular in size, varying from 0.5 to 1.5 of the normal, but poikilocytes were few in number. Numerous specimens of blood taken at night failed to show evidence of filaria. The only suggestion as to the nature of the case was that it might be a variant of Milroy's disease, but there is an entire absence of hereditary element.

Archives des Maladies de l'App. Digestif, Paris

July, 1919, 10, No. 4

*Lambdia Enteritis. A. Cade and A. C. Hollande.—p. 193.

*Mucous Gastric Catarrh. L. Pron.—p. 223.

*Gumma in Cecum. D. Giordano.—p. 236.

Intestinal Lambliosis.—Cade and Hollande describe with minute detail ten cases of chronic diarrhea in which *Giardia (Lamblia) intestinalis* was found. Its exclusive pathogenic rôle was demonstrated in these cases. Fairise and Jannin even found the parasite burrowing deep in the bowel wall, but there is a possibility in their case that the patient may have had a preceding dysentery. The parasites encased in the walls escape the action of drugs by the month. Experience and review of the literature seem to show that neosarsphenamin by the vein is the most effective treatment known to date. The predominant symptom is diarrhea, and it may develop gradually or with an acute onset resembling dysentery. Formed stools are extremely rare, but there is little subjective disturbance even during the exacerbations. The liver is not enlarged, but the colon is somewhat tender and the left "colonic cord" is distinct. The patients are usually thin and pale but not enough to harmonize with the long duration of the affection. The temperature may keep normal over long periods, but they often noted slight evening rises, and in one case there was high fever at times. There are no striking blood changes, and they never found pus in the stools with lambliosis. No improvement was noted in two of three cases under hydrochloric acid, but in the third case the benefit was pronounced, and the cysts of the lamblia disappeared from the stools (two examinations). From 1 to 1.5 gm. of the hydrochloric acid was taken daily in "albumin-

ous water" for twenty or thirty days. (The *can albumineuse* of the French Codex is made with the whites of four eggs beaten up in 1 liter of water, flavored with orange-flower water.)

Mucous Gastric Catarrh.—Pron emphasizes that continuous or exaggerated secretion of gastric juice is not all that comes under the heading of gastric catarrh. When splashing can be heard in the stomach twelve or fourteen hours after the last meal, and a thick alkaline, neutral or only slightly acid fluid can be aspirated then from the stomach, there is evidently mucous catarrh alone. Saliva floats on the stomach content and does not blend with it, and mucus from the esophagus is more fluid and clearer; it filters readily, and the chlorid content is small, differing widely in these respects from gastric mucus, which looks more like a thick solution of acacia. On centrifugation it yields a thick clot formed exclusively of ricelike granules which are dissolved by acetic acid. He has encountered 21 cases of this mucous catarrh, including 7 in which there was accompanying slight acid hypersecretion. Some of these patients present the clinical picture of continuous hypersecretion, others of hyposecretion with little appetite, and oppression after dinner. Some complain of pain in the bowels in the morning, probably from difficulty in passage of the thick mucus through the bowel. Vomiting of mucus was known in only 4 of his 21 cases. The other symptoms are those of ordinary gastric disturbance except that there was enterocolitis in 7 of the 21 cases. The excessive secretion of mucus interferes with digestion in the stomach, it weighs down the organ and by modifying the concentration of the stomach contents retards the opening of the pylorus. The aim in treatment is to keep the mucus dissolved, and for this alkalines are required, such as half a glass of Vichy water taken tepid before breakfast. Sodium carbonate, 0.5 gm. in water, at the close of meals, has proved useful in some but not in all cases. In infants, Gauthely was successful in the graver forms with rinsing out the stomach with Vals mineral water three times a day. The diet should exclude soft foods like purées, milk, etc., which only augment the mechanical disturbance. Salt, condiments and carbonated mineral waters help in the evacuation of the stomach, and a correctly applied band to sustain the sagging organs, and also hydrotherapy may be useful. The diet should differ according to the type of reactions; when they are sluggish and gastric secretion is low, meat, with salt and condiments may stimulate the stomach, aided perhaps by hydrochloric acid, 10 drops in half a glass of water at the beginning of the meals, supplemented by nuxvomica to promote the evacuation of the stomach. With a lively reaction, meat and condiments should be avoided, giving the preference to fish, green vegetables and eggs, taking hot sage tea in the morning, fasting, and giving belladonna to soothe the stomach mucosa, and after meals a tablespoonful of a mixture of 3 gm. each of sodium sulphate, sodium phosphate and sodium bromid in 300 gm. distilled water.

Gumma in Cecum.—The gumma was discovered during an appendicectomy, and Giordano removed the segment of the cecum along with the appendix.

Conc'n.

Calculi in Urethra.—Van den Branden reports a case of acute recent gonorrhea with pain on micturition, and about the fifth day a hard tender tumor was palpated 2 cm. from the meatus. The tumor was treated on the assumption of an acute inflammatory process in Littre's glands, which the palpation findings seemed to indicate. They persisted unmodified for two weeks. Then endoscopy revealed the tumor to be a calculus, 1 by 1.5 by 0.5 cm. Strictures had developed at this point during these two weeks. There never had been any symptoms from the urinary apparatus before the gonor-

rhea, and the assumption of an acute litritis seemed unquestionable, until the calculus was discovered.

Erythema Nodosum and Acute Endocarditis in Boy of Eight. De Meuron—p. 428.

Urea Content of Blood of Children.—Van der Starp has modified the Ambard ureometer so that it can be used with only 1 c.c. of blood. The blood is drawn directly into 3 c.c. of a 0.1 per cent. solution of potassium oxalate. The whole blood is used, and it is drawn into this hemolyzing and coagulation-preventing fluid, and the ureometer is graduated for hundredths of cubic centimeters. No centrifuging is required, and the whole procedure is so simple and easy, he declares, that the busy practitioner can thus conveniently inform himself in regard to the work of the kidneys, even in infants, applying the Ambard formula from the ureometer findings. The ureometer is based on the alkaline bromid reaction, which he regards as the most reliable test. This method has hitherto had to contend with the drawback that 20 c.c. of blood were required for it. An illustrated description is given of the modified ureometer which works with only 1 c.c. of blood.

Phimosi in Infants.—Phélip and Galard have been reexamining recently 51 children who had been operated on for phimosi some time before. In every case in which there had been balanoposthitis, it promptly healed after the operation for the phimosi. With incontinence of urine, the operation was followed by a complete cure only in 7 of the 18 cases but some improvement was manifest in 5 others. In one case showing no improvement, an operation on adenoids later was followed by improvement. With incontinence, other possible causes aside from the phimosi should be sought. If the meatus is unduly narrow, this is easily corrected as a rule by mechanical dilatation.

- *Abdominal Cesarean Section. P. Bar—p. 49.
*Breech Presentation with Fetus in Hyperextension. A. Laffont—p. 62.

Abdominal Cesarean Section.—Bar draws the balance sheet of high cesarean section, his conclusion being that it is almost certain to be a success for the mother and is absolutely certain for the child when the woman is not threatened with infection and the environment can be counted on and the simple technique is applied by not unskilled hands. The indications for it are when the bones or soft parts offer an obstacle that renders natural delivery improbable, and when circumstances compel rapid evacuation of the uterus while the fetus is still undilated. Its most promising field is as a prophylactic measure, early in labor or before labor has begun.

Breech Presentation with Hyperextension. The child of a woman who had a myopia showed that the bending of the body on the spine during the course of the labor, when the fetus had prevented the normal development of the fetus, had caused the hyperextension of the fetus. The hyperextension of the fetus during delivery had caused the hyperextension of the spine. Nothing was found to explain the hyperextension of the fetus before labor. The hyperextension of the fetus in the few instances of total hyperextension on record, as well as with breech presentation. Infant born with breech presentation are hydrocephalous in about 20 per cent. of the cases, from the pressure of the wall of the uterus on the head. The hyperextension predisposes to breech presentation. Slow delivery is the safest; rapid delivery, suddenly straightening the neck, is liable to rupture the dura or do other damage. A certain number of instances of paralysis of the brachial plexus may be traceable to some injury from forcible straightening when there has been breech presentation.

Local Arterial Blood Pressure in Diagnosis of Varicose Conditions and in Control of Treatment. L. Michéle—p. 148.

Reinforced Rubber Endoprostheses.—Delbet and his co-workers have previously reported their experiments with rubber implants to replace lost segments of bone, and they here give the details of two successful clinical cases. The gap in the radius crippled the men completely. The stumps were fitted each with a cover, and an adjustable reinforced rubber interpiece was fitted in between these covers. The bone recovered its normal length and strength at once. The results seventy and eighty-eight days to date are perfect both from the orthopedic and functional points of view, aside from a preexisting paralysis in one case.

Surgical Correction of Wrinkles.—Practically the same article was summarized recently, July 5, 1919, p. 70.

Serothrapy and Traumatic Shock.—Bouchet lauds the efficacy of a polyvalent antiserum (LeClanche and Vallée) both in prevention and in treatment of traumatic shock. No shock developed in 75 gravely wounded men treated with it, and the symptoms of established shock retrogressed in twelve others.

Actinomycosis of the Heart.—Letulle and Hufnagel describe in minute detail a case of actinomycosis of the entire heart and pericardium, inducing extensive lesions. The patient was a man of 34 and the actinomycosis seemed to have started first in the esophagus and spread thence to the heart and secondarily to the right pleura and base of right lung. The case confirms that wherever the actinomycosis proliferates, it destroys all the tissues and organs in its way, whatever their structure.

*Seasickness. P. Czamman—p. 638.
*Committee Report on Isolation of the Tuberculous—p. 641.

Lethargic Encephalitis.—Lhermitte and Saint-Martin report a case, with recovery, of what they call primary poliomyeloencephalitis with narcolepsy, or opthalmoplegic encephalitis with narcolepsy. The mesocephalic region seems to be primarily affected, and the usual term, lethargic encephalitis, is too broad. They comment on the remarkable absence of any changes in the fundus in their numerous cases of this kind, also the absence of albuminosis and of pleiocytosis in the spinal fluid, the absence of the Argyll Robertson sign and the negative Bordet-Wassermann reaction. They treated all these patients with hexamethylenamin by the mouth and there were no deaths in their series. The case here reported was exceptionally severe, and they gave, besides, three daily intravenous injections of 1 or 1.25 gm. of hexamethylenamin, at the same time withdrawing 0.5 c.c. fluid by lumbar puncture just before the third injection. The secretion of the choroid plexuses is assumed to be activated by this, and thus to allow more of the drug to pass into the cerebrospinal fluid. Be this as it may, the patient's condition improved totally at once and the procedure seemed absolutely harmless. The first intravenous injection had been supplemented only by a dose of 1 gm. of the same drug by the mouth. The first symptoms had been noted ten days before.

Death in Influenza.—Renaud's analysis of the lesions in the fatal cases of influenza and of the mechanism of death

has convinced him that instead of speaking of "influenza in a pulmonary form" we should define it as "a pneumococcus infection of the lung, epidemic and contagious." This conception entails the practical conclusion that every case of influenza, even the mildest form, should be regarded as potentially grave and should be treated accordingly (bed rest, baths, preventive digitalis). It shows further the utility of all the measures when applied late, after the inevitably fatal process is well under way. It assures us, moreover, that treatment will be effectual in the immense majority of cases. In his service, treatment based on these premises and applied with increasing confidence brought the mortality down from 7 per cent. (May-December, 1918) to 2.5 (December-March, 1919) and to 0.2 per cent. (February-April), although the proportion of grave pulmonary forms was highest in the latest series. These premises also justified the simultaneous injection by the vein of epinephrin and anti-pneumococcus serum which brought on without fail a crisis identical in every respect with the salutary crisis of frank pneumonia, all the twenty-seven thus treated recovering rapidly and completely although they were the gravest cases in a series of 130. "The disease is in the lungs but the outcome depends on the heart." Multiple and extensive foci of hepatization in the lungs were found in all the fatal cases. This entails asphyxia, and heart failure completes the vicious circle. Treatment should be based on physiology. Even in threatening cases, simple hygiene and dieting, with a few cold packs often averted the disease in two days.

Acute Yellow Atrophy of the Liver.—Garnier and Reilly report four cases of infectious jaundice which differed in many respects from icterohemorrhagic spirochetosis, although occurring under similar conditions. No micro-organisms could be discovered, but necropsy revealed typical acute yellow atrophy of the liver. The men died from two to four days after the first appreciable symptoms. The jaundice from spirochetosis seldom proves fatal before the eighth to the thirteenth day and the symptoms are more from the kidneys than from the liver.

Malaria and Diarrhea.—Joh and Hirtzmann warn that malarial diarrhea is not uncommon but may be mistaken for dysentery. The laboratory excludes the latter, and the way in which the diarrhea subsides under quinin confirms the malarial origin, or the aggravation of a pre-existing enteritis by the malaria.

Seasickness.—Cazamian is the chief medical officer on the cruiser *Jean-Bart*, and he has made a special study of fifty cases of seasickness during the last two years. This has convinced him that the abnormal sensations and stimuli induced by the movements of the ship act on the nervous system of the vegetative life (autonomic and sympathetic nerves). The sympathetic nervous system thus becomes irritated. Its hyperexcitability is manifested in the higher blood pressure, tachycardia, inversion of the oculocardiac reflex, and dilation of the pupils. The symptoms suggest excessive production of epinephrin at first. Then the suprarenals become exhausted, and the blood pressure drops. During the first phase there is a sympathetotonic paroxysm; during the second phase the clinical and pathogenic phenomena are like those of shock. Persons inclined to sympathetotony are peculiarly predisposed to seasickness while the vagotonic escape. In the second phase, epinephrin by the mouth (6 mg. in three doses at half hour intervals), gives good results, but it is of course directly contraindicated during the first phase, the hyperepinephrin stage. During this phase, he has obtained absolutely constant excellent results, both in prevention and in curing the seasickness, from hypodermic injections of neutral sulphate of atropin in doses varying from 0.001 to 0.002 gm. As we know of no drug that will check the functioning of the sympathetic nerve, the next best thing is to act on the antagonist nervous system. By influencing the vagus in this way with atropin, we thus indirectly control the sympathetic. The question whether epinephrin or atropin is called for in the individual case is easily answered by the oculocardiac reflex. His experience indicates that with one or the other of these two drugs we can ward off and cure seasickness, he reiterates in conclusion.

Hemophilic Joints.—Escande and Tapie analyze the roentgen findings in the knees of a hemophilic boy of 9. The tendency to purpura and joint affections was noted from the age of 4 and 10 months. The recurring hemarthrosis of the knees had crippled the boy from the resulting chronic panarthrosis which at first suggested tuberculosis. Addition of an emulsion of normal blood corpuscles to the boy's blood corrected the delay in the coagulation, confirming the assumption that the blood in hemophilia is lacking in certain ferments of leukocyte origin. No tendency to hemophilia could be detected in other members and branches of the family but the blood findings are of the familial type, suggesting that this boy is the first of a line of bleeders. The roentgen findings in the joints differ with each case, but in this boy all the features of the other cases on record seem to be combined.

Radiotherapy of Brain Tumors.—Nordentoft has now a record of eighteen cases of brain tumors given roentgen treatment since February, 1915. Nine of these patients are living and in good health, except hemianopsia in one case, and that vision is rather poor in another case in which the patient had been almost completely blind before the radiotherapy. (A previous communication from him on this subject was briefly summarized in these columns, May 18, 1918, p. 1510.) He describes here two especially striking cases, one in a young lawyer who had become imbecile, with incontinence of both stools and urine. It proved impossible to localize the assumed tumor, which was supposed to be a diffuse glioma, presumably in the frontal lobe, and the entire head was submitted to cross-fire exposures, brow, parietal and temporal regions, omitting only the occiput as this was so difficult to reach. The aluminum filter was 10 mm. thick and the rays were applied until depilation was complete. Improvement was evident by the fifth or sixth day, and recuperation was soon complete, so that the patient was able to resume the practice of law. In two cases of cerebellar tumors the permanent cure was soon realized; a third in this group died, and the fourth did not seem to improve except that the course of the tumor was arrested. An operation some time later revealed a cyst in the cerebellum, and the patient recovered after the cyst had been drained. There is a possibility that the cyst had developed in the space left by the healing of a tumor under the preceding roentgen treatment.

Roentgenogram of Guinea-Worm.—The roentgen picture of the leg shows very clearly a long narrow, dark mass which feels under palpation like the intestine with the bismuth suspension. The only explanation possible, Delort says, is that the shadow is cast by an old calcified *Filaria medinensis*. The patient is a native of the tropics.

- *The Arterial Pressure During Bombardment. G. Etienne and G. Ruyard.—p. 109.
*Chemistry of the Intestines. R. Gauthier, R. G. and Barato.—p. 115.

Blood Pressure During Bombardment.—Etienne and Richard write from Nancy: "Several years of medical observation in a bombarded city have attracted our attention to the rôle which war emotions may play in respect to the state of the arterial tension." Since they began to study it (January, 1916), a number of communications on this subject have appeared, but they all related to soldiers, that is, to healthy young men. Their Nancy report deals with 100 subjects of all ages, many examined repeatedly during the years of bombardment as they sought shelter in a certain cellar. The findings confirm that every violent emotion modifies the arterial pressure, usually sending it up for five or ten minutes and then it drops below normal for a few minutes to two or three hours. Exceptionally, and only in the young, there is primary hypotension with tachycardia. The blood pressure returns to normal in the young under repeated or continued emotional stress much sooner than in the elderly. The latter may still show hypotension months after the danger is past. The data accumulated in this research confirm that very intense fear has an inhibiting or even a destructive action on the suprarenals, but less intense emotional stress has merely a stimulating action on them, inducing excessive production of epinephrin. With recurring fear, as in a bombarded town, the suprarenals are kept in a chronic state of excessive production of epinephrin, and this keeps up a chronic overstimulation of the sympathetic system with all that this implies for the whole endocrine and vasomotor systems.

Chemistry of the Intestines.—The duodenal juice was examined separately and the findings were compared with those from analysis of the stools. Gaultier and his co-workers tested the duodenal juice for bile pigments with Fauchet's reaction and the stools for pancreatic juice by titration with commercial pancreatin. They tabulate the findings in five normal persons and in eight with various gastro-intestinal disturbances. They found that the coprologic examination usually gave results that harmonized with the duodenal juice findings, thus completing the oversight of bowel functioning. But analysis of the stools was far more instructive than of the duodenal juice as the information it imparts bears on the sum total of the digestive activities, instead of the partial information which is all that can be learned from the duodenal content.

Aug. 16, 1919, 9, No. 33

*Treatments by the Mouth of Chronic Amebiasis. P. Ravaut and Charpin.—p. 175.

*Undulant Fever from Hidden Diseased Glands. P. Harvier.—p. 130.

*History of Traumatic Commotion. R. Benon.—p. 137.

Treatment of Chronic Amebiasis. Ravaut and Charpin expatiate on the necessity for varying the treatment of rebellious chronic amebiasis to conform to current conditions. They have obtained gratifying results with a paste made of charcoal, bismuth and ipecac, alternating this with neosarsphenamin. This treatment, entirely by the mouth, is well tolerated; it soothes the intestinal disturbances and seems to act rapidly on the parasites. It does not depress the appetite, which is very important, as the patient is saved if he eats, assimilates and increases in weight. Small enemas of neosarsphenamin usually supplement other measures, using not more than 0.15 or 0.30 gm. in 50 or 100 gm. of water, so that it will be retained. The paste mixture they use contains 100 gm. each of pulverized wood charcoal, bismuth subnitrate, simple syrup and glycerin, with 4 gm. of pulverized ipecac. This is 0.1 gm. of ipecac to the teaspoonful, and from two to ten teaspoonfuls are taken during the twenty-four hours. If there is violent diarrhea, with pains, they add 0.80 gm. of pulverized opium to the above mixture. This paste is taken for one day, the second day one or two capsules of 0.10 gm. neosarsphenamin (novarsenobenzol); the third day the paste again, and the fourth neosarsphenamin, and so on alternately. In the five cases described, the men bore this treatment without nausea or colic, and one increased 5 kg. in weight in five months and another gained 2.2 kg. in forty-five days. A marked influence on the parasites was evident in three cases but not in the two others, although the men were gaining in weight and strength,

weighing 6 and 10 kg. more in two months, and the stools were frequently although not always free from the parasites.

Fever from Deep-Seated Glandular Disease.—Harvier gives charts from three cases in which a wave-like fever suggested Malta or undulant fever. There were afebrile periods in three, lasting for two to five days. One patient had eight of these waves, each from nine to fourteen days long. In three others the temperature did not drop quite to normal in the intervals. The spleen was enlarged in all but the liver seemed to be normal. There was also moderate anemia, but no change in the leukocyte numbers or formula, and no pathologic peripheral glands. Necropsy in three cases described in detail revealed a severe glandular process deep in the abdomen or mediastinum. In one of these cases, the primary mediastinal adenopathy had been followed by other lesions of other glands in the groin and elsewhere. As each of these glands became involved, a new wave of fever was observed. Undulant fever, therefore, should suggest a possible deep-seated adenopathy which raying might reveal.

Traumatic Commotion.—Benon reviews the earlier works on railway spine, railway brain, traumatic asthenia, citing as the pioneers Dupuytren in France (1832), Erickson in England (1886) and Knapp in America (1888). In Dupuytren's work we find the exact description of transient or prolonged traumatic asthenia just as it is encountered today.

*Pregnancy with Diseased Heart, Lungs or Kidneys. P. Hussy.—p. 1145.

*Functions of the Cerebellum and Adjacent Organs. E. Rothlin.—p. 1161. Com'd in No. 30, p. 1113.

*Respiration Curve at the Apex. E. Strümann.—p. 1171.

Outcome of Heart, Lung and Kidney Disease After a Pregnancy.—Hussy states that of the 15,352 parturients delivered at the Basel Women's Hospital in the ten years ending with 1917, 35 had heart disease and 9 per cent. of these died at delivery and 18 per cent. not long after. In 40 per cent. the disease had evidently been aggravated by the pregnancy, and only 50 per cent. seemed to bear the pregnancy and delivery without harm. In 17 per cent. the condition became aggravated during the pregnancy, and abortion had to be induced. Of the 76 parturients with manifest pulmonary tuberculosis, 6 per cent. succumbed at delivery and 10 per cent. soon after; 17 per cent. had the condition aggravated during the pregnancy, but 60 per cent. passed through the pregnancy apparently unharmed by it although in this group 8 per cent. showed an aggravation during parturition. Of the 15 women with chronic nephritis, 20 per cent. died at delivery and only 43 per cent. passed through the pregnancy without aggravation.

of the kidney disease. His figures show further that very few of the women with mitral stenosis survived their pregnancy, some dying before delivery. On the other hand, latent pulmonary tuberculosis did not seem to be much influenced by the pregnancy, and even in the manifest forms the condition seemed to improve. The women may succumb a few years afterward to the aggravation of the condition by the propagation of the bacilli at the time of the delivery; the pregnancy in itself does not seem to entail aggravation. With chronic nephritis, the primary mortality was high, but after delivery the condition seemed to improve. Hussy compares these experiences with those of others in this line.

The Functions of the Cerebellum.—Rothlin's extensive experimental research and clinical experience confirm Bolk's statements as to the localization of certain motor centers in the cerebellum. When the anterior lobe of the cerebellum is irritated with curare, the symptoms observed are not traceable to the cerebellum, as Pagano insists, but to the action of the poison on the adjacent organs, especially the fourth ventricle.

Respiration Curve at the Apex.—Stirnemann refers particularly to the curve in children and youths recorded with the Jaquet sphygmocardiograph and three Marey drums, one for each apex and one for the chest expansion. These three simultaneous and symmetrical curves show always in health well defined high peaks, nearly symmetrical. The difference is striking in the pathologic cases, even with incipient disease. He gives typical curves, and commends this method as very instructive in detection of the earliest phases of apical disease in the young.

Remineralization of the Organism.—Baccarani insists that mineral salts in the form of drugs are utilized far less than the mineral salts found in certain plants, seeds, etc. These he calls "living mineral salts" and urges their systematic use in therapeutics, but does not specify what seeds or amounts he gives in the mixture he uses.

Rivista di Clinica Pediatrica, Florence

July, 1919, 17, No. 7

*Esophagoscopy. A. Orlandini.—p. 337.

Appendicitis Secondary to Scarlet Fever. A. L. Canelli.—p. 362.

Esophagoscopy.—Orlandini used a small straight spatula tube, perforated, with a right-angled handle, for direct esophagoscopy in two children recently, and it worked like a charm. One child was 2½ years old and the other 18 months, and no anesthetic was used. The subject sits in a low chair, only 15 cm. high, with back and arms and a horizontal extension 1.30 meters long, with adjustable cross-bar for the feet to brace against. The physician sits on a high chair, 70 cm. high, that straddles the low extension and the patient's legs. The patient is thus restrained from moving while his head is held from behind by a nurse. This arrangement is peculiarly advantageous for anesthesia and for various operations as the patient is comfortable as if sitting up in bed, while the arms of his chair hold his trunk and pelvis firm and his legs are held between the legs of the tall chair and the physician's legs as the latter sits in the high chair the seat of which tilts forward a trifle. When the patient is a small child, the nurse sits in the low chair holding the child.

In the 2 year old child the tube was passed safely down to below 13 cm. but then the child suffocated, and the tube had to be withdrawn and artificial respiration applied for ten minutes. When all was in order again, the tube was passed easily down beyond this point, but was then arrested by the bulging mucosa. The probe gave the impression of a foreign

body below this. A smaller tube was then introduced through the first tube, and this passed the obstacle with a sudden jerk as if a solid foreign body had been dislodged. The lumen filled up at once with thick mucus, slightly blood streaked, and a scrap of a chestnut was found in it. The larger tube could then be pushed down to the stomach. As it was withdrawn, the walls of the esophagus were seen to be normal all the way, and its permeability had been completely restored. The whole chestnut had been swallowed over two months before this procedure. The first two weeks the esophagus had been completely obstructed; after this, fluids could be swallowed. The chestnut had probably been impacted first at the root of the neck, and had later dropped down to the constriction of the thoracic segment, 17 cm. from the teeth. The symptoms were the usual vomiting and metallic, spasmodic cough whenever food was taken, with occasional attacks of suffocation but no pain. With a foreign body in the air passages there is pain during breathing and speaking, and the child refrains from moving about and speaking. The great danger is that the foreign body will be overlooked and the disturbances ascribed to stomach disease.

This method of introducing one endoscopic tube inside of another when the first is arrested by some obstruction, has been successfully applied by Orlandini in cases of chronic stenosis of the bronchi, without complicated apparatus. In the case described above, various other measures had been tried before but all had failed, including local application of epinephrin and cocaine on probes, seeking thus to induce the subsidence of the protruding mucosa. In his second case the esophagoscope revealed the foreign body about 15 cm. from the teeth and showed an inflammatory reaction around it. Aspiration through the tube dislodged the chestnut and it dropped into the stomach. The 18 months infant bore the esophagoscopy well, without much salivation, but finally showed signs of suffocation and the tube was removed. When introduced anew, the foreign body had vanished. In both cases the foreign body was a nut, a *castanea* and a *marron*, not metal. And neither of the children seemed to experience any ill effects afterward. He mentions parenthetically a case in which a foreign body was expelled spontaneously after the boy of 8 had drunk 100 gm. olive oil and 1,300 c.c. of tepid boiled water, and had been placed slanting on the table, the head pendent, and his throat tickled with a feather. He first vomited a small amount and then came a gush that swept out the foreign body, a cravat holder, which he had been using for a whistle.

*Prophylaxis of Trachoma. R. David de Saion.—p. 234.

*Intermittent Fever in Third Stage of Syphilis. A. de Medeiros.—p. 248.

Pathogenic Action of Trichocephalus.—Fernandes found intestinal parasites in 89 per cent. of 101 children at the children's clinic at Rio de Janeiro. In 15 the trichocephalus was discovered, and all in this group had had bowel trouble, but in another group of 12 the trichocephalus was found but bowel functioning had been normal. In a third group of 6 there had been bowel trouble but no parasites were discovered. In all but 4 of 62 living children examined, ascariides were associated with the trichocephalus in the stools, but blood was found only in 29 per cent. of the 58 trichocephalus cases. He was unable to discover any evidence of a constant specific anemia due to the presence of the trichocephalus, and he never found visible blood in the trichocephalus parasites although they often gave a positive response to the benzidin blood test. A trichocephalus preparation made and applied like tuberculin never elicited a positive reaction, and children with the trichocephalus in the stools but no bowel disturbance were repeatedly encountered. He gives an illustration of a segment of the intestine of a child which was studied with adherent specimens of the trichocephalus. The child had died from chronic enteritis, but at the points where the parasites were adherent the tissues seemed to be quite sound.

case some syphilitic process had probably induced diffuse infiltration involving the optic chiasma and the pituitary body.

- *Radium Treatment of Cancer of Uterine Cervix. S. Recasens.—p. 241.
*Spinal Anesthesia in Gynecology. I. Navarro Blanco.—p. 247.
Histogenesis of Corpus Luteum. L. G. Gullera Moss.—p. 255.

Doses for Radium Treatment of Cancer of Uterine Cervix.—Recasens warns that low numbers of leukocytes formally contraindicate large doses in radium treatment. The patients as a rule bear medium doses, frequently repeated, better than large doses at longer intervals. Exposures for more than twenty-four hours at a time are not borne well, as a rule. Prolonged fever also requires suspension of the treatment. He regards radium treatment as the chosen method of treatment for cancer of the uterine cervix, unless it is so small and circumscribed that it is possible to eliminate all the neoplastic elements with operative removal of the tumor. In conclusion he specifies as beyond our skill the cases of cancer of the cervix in which profuse hemorrhage results from the eroding of the walls of the larger vessels. If two or three applications of large doses of radium do not rapidly arrest the disease, it is better to desist and to regard the case as beyond our best efforts.

Spinal Anesthesia in Gynecology.—Navarro expatiates on the superior advantages of the subarachnoid technic when an operation on the vagina promises to be long and tedious. Its great drawback is the liability to headache and fever, but the headache, although annoying, is not dangerous. About a third of his patients experienced it; it was usually mild but in some cases was very severe and persisting. He has never witnessed postoperative nausea or vomiting with this technic, nor any disturbance in respiration or the circulation or nervous system with the exception of one case in which bulbar symptoms developed but soon subsided under stimulants and hot compresses on the precordial region. With this technic, one assistant can be dispensed with. Another advantage is that the anesthesia is of the conductive localized type, and the bronchi and heart are not affected as with inhalation of anesthetics. The temperature usually runs up but this is not accompanied by any signs of fever; the pulse keeps normal and there does not seem to be any connection between the intensity of the fever and the other symptoms.

Necessity for Systems of Geritons Midwifery. J. A. Berni.—p. 579.
The Public Health in Spain and in Argentina. E. R. Goni.—p. 580.

Varicocele.—In this profusely illustrated article, Finocchio analyzes the experiences with eighty cases of varicocele, all on the left side, with operative treatment in all but eleven cases. The ideal treatment is to dissect out the spermatic artery and transplant the veins inside the abdomen. The more practicable procedure is the high separation of the spermatic artery and resection of the veins accompanying it, with transperitoneal transplantation of the anterior bunch of veins, with care not to kink or injure them.

Pyoculture.—This term was devised to express the systematic cultivation of germs from the pus of wounds as a means of keeping oversight of its course. The pus is taken with a pipet close to the tissues; the tip is then fused and the pipet incubated for from twenty to twenty-four hours. The tip is then broken off and the pus is spread on a slide and a bouillon culture is also made. This procedure is repeated, and it is by comparison of three successive slides that the course of the suppuration can be estimated accord-

ing as the different bacteria grow more numerous or less, and as their proportionate numbers vary. A negative pyoculture may contraindicate amputation when the clinical condition seems to demand it, and successive pyocultures give an insight into conditions, it is said, far beyond anything otherwise attainable.

Pediatrics in Argentina.—This is the inaugural lecture of Professor Acuña's regular course in pediatrics, and of Velasco's "free" course in the same subject.

Morbidity of the Teeth Secondary to Nutritional Disorder.—Castilla has been making a special study of the relations between anomalies and caries in the teeth and gastrointestinal derangement. He found that children with a history of nutritional disorders frequently had abnormal teeth, the enamel was less perfect and tartar and caries were frequent. Children who seemed to have kept in good health had much more perfect teeth than those with a gastrointestinal past, especially colitis. He noted also that the intensity of the morbid changes in the teeth were always proportional to the duration and intensity of the nutritional process. These changes in the teeth were found in children of 1½ to 4 years old. In older children, apparently healthy but with these changes in the teeth, investigation of the antecedents nearly always disclosed the same causes as in the others. Removal of the tartar only transiently arrests the process.

Siglo Médico, Madrid

- *Histopathology of the Spleen in Banti's Disease. F. Jiménez Asúa.—p. 533.
*Immunization against Necrosis. Camilo Calleja.—p. 536.
Inebriety with Crises of Mania. A. Sánchez Herrero.—p. 538.

Histopathology of the Spleen in Banti's Disease.—The research here reported by Jiménez was undertaken under a grant from the Junta para ampliación de estudios en el extranjero. The work was done at the Instituto de Anatomía Patológica at Naples. Nothing suggesting tuberculosis, syphilis, malaria or streptothrix lesions could be detected in the spleen in the six cases of Banti's disease described in detail. No one yet has succeeded in reproducing the disease by inoculation or by cultivation of germs from it. Jiménez is convinced that it has no specific agent, but that ordinary toxoinfections in persons predisposed thereto are liable to whip up the functioning of the spleen and entail finally a tendency to fibrous degeneration of the gland. He found this fibroadenia in every one of the spleens examined, although in different phases of the process. The liver may long escape in which case the disease may be classed as merely splenic anemia, but closer study of such cases and their ultimate course confirm their identity with the first stage of Banti's disease.

Immunization Against Necrosis.—Calleja explains that the derivatives of empiric medicine, the blisters, the fixation abscesses, etc., owe their efficacy to the fact that they induce an active and a passive immunization against the effects of the necrosis of the tissues in the disease process. Subcutaneous injection of 3 or 4 drops of chloroform at different points, to a total of from 3 to 50 c.c., is a convenient method of this "causticotherapy," and it can be usefully supplemented with horse serum prepared like diphtheria antitoxin, only using, instead of diphtheria bacilli, human tissue scraped rendered necrotic with chloroform. The aim in treatment is to immunize against necrosis, not to combat the inflammation, etc., which latter are salutary reactions on the part of the tissues. Antinecrotic immunization by this causticotherapy.

as probable he reiterates, as a preventive adjuvant in the early treatment of acute disease, such as pneumonia, of the "shock." But its special field, he adds, is in the prevention of the disease, immunizing the patient against the products generated by the disease, instead of wasting time in the usual efforts to combat the symptomatic manifestations of the curative reaction, either toward restitution or substitution. This immunization is realized, he explains, by the polypeptides formed by the dissolution of the cancer cells, but it is necessary to keep these cytolytic substances below the amounts that would do damage from excessive action. Callera quotes from Turck's work, and reiterates that we must remember that bacteria are not like seeds. Seeds are sown in an inert soil, and all the development that results is in the seed and the resulting plant. Infection, on the other hand, is like a fecundation, in which the body cells are the fecundated elements. By immunizing against any resulting necrosis, we may be able to shorten the course of tuberculosis and joint disease and reduce the mortality.

Chronic Aspiration of Food Particles Into Lung.—Roentgen examination showed numerous particles of food in the lungs of a previously healthy man of 50 who for the last year had had increasing difficulty in swallow. After a bismuth meal some of the bismuth was seen in the lungs, and a communication with the air passages was assumed as the assumption of cancer seemed probable. Necropsy failed to show any communication, however, and the only explanation of the findings must be that the food, meeting the obstruction in the esophagus, was coughed up each time, and instead of being expelled passed over into the air passages. The absence of any inflammatory reaction to the food particles was a remarkable feature of the case.

Hospitalstidende, Copenhagen

July 23, 1919, 62, No.

Medical Education of Germany. E. Henningsen.—p. 873.

Medical Education for Rabid Paralysis. Id.—p. 881.

Retrograde Incarceration of Hernia.—Henningsen in the last two, and a half years has encountered three cases of this kind, the series illustrating the various steps of the process. The patients were adults with inguinal hernia of long standing. He refers to the literature on retrograde incarceration, remarking that the diagnosis has seldom been made before, but it might be suggested by the severe general symptoms and the signs of beginning peritonitis when a hernia is incarcerated without showing much in the way of local symptoms. The outlook is much graver, naturally, than in retrograde incarceration, on account of the disturbance of the blood supply. In Wendt's compilation of seventy-four cases, 23 per cent. was resected; 62.5 per cent. in the twenty-four cases of his own series was resected; five died of the six resected, and five died after the intestine was resected. The total mortality was 42.7 per cent. In the present series, the operation was operated in two only, and the results were not so good, and the incarceration was not so serious. The mortality was readily reduced. The results of the operation are not yet clear, but it is to be understood the resection was not performed.

Fascia Transplantation to Correct Radial Paralysis.—Henningsen reports the results of the correction of radial paralysis in a child by the use of a strip of fascia from the human leg. The operation consisted in a strip, taken from the fascia lata of the leg, was cut to the extent of 10 cm., and then sutured to the muscle and to the radius. The arm was fastened under the peritoneum while the hand was held supine and extended. This leaves all the muscles

of the arm intact, in case the paralysis should happen to regress later. The boy now uses this hand as well as the other, and electric tests indicate beginning regeneration of the radial nerve.

Taberculin Skin Tests as Anatomist. H. Hopstock.—p. 417.

Taberculin Skin Tests in Influenza. K. Nicolaysen.—p. 502.

Taberculin Skin Tests of Schoolchildren at Trondhjem. A. Arnfinnsen.—p. 508.

Convalescents' Serum in Treatment of Influenza. J. Holst.—p. 534.

Da Vinci, the Anatomist.—Hopstock gives photographic reproductions of a large number of da Vinci's famous anatomical drawings which he has been studying and interpreting under a special grant from the university. He declares that da Vinci's work placed him centuries ahead of his contemporaries in knowledge and thought, "a modern biologist in the guise of a medieval artist."

Duodenal Ulcer in Influenza.—Nicolaysen found a duodenal ulcer at necropsy in two cases of influenzal pneumonia. The ulcers seemed to be quite recent, and there seem to be grounds for assuming that they were of infectious origin. Diplostreptococci were found in the lungs and also in the duodenal ulcers. Micro-organisms were found likewise in a duodenal ulcer in a man of 50 who had died from acute myelogenous leukemia.

Tuberculin Skin Tests in Schoolchildren.—Arnfinnsen gives a number of large tables showing the response to the Pirquet skin tuberculin tests in 7,969 schoolchildren. It was positive in 37.8 per cent. of the 9,978 in the public schools and in 33 per cent. of the 991 in private schools.

Convalescents' Serum in Influenza.—Holst analyzes his experience with twenty cases of influenza pneumonia in which he gave intramuscular injections of from 10 to 33 c.c. of serum from convalescents' blood, repeated from two to four times. In ten cases the crisis followed the day after the injection. In the other ten no benefit was apparent, and seven of the patients died.

Weather and Neuroses. J. Mygge.—p. 1239.

Weather and Neuroses.—Mygge remarks that twenty years ago any physician who ascribed pathogenic importance to meteorologic conditions was ridiculed, but the progress of science, heliotherapy, etc., have demonstrated the importance of such factors. He presents further evidence to sustain the assumption that the periodical transient and apparently un-motivated pains and other ill feelings of which certain persons complain are connected with certain changes in weather conditions. They are mostly persons with a predisposition to rheumatism or joint troubles. It is not correct to call them "barometer individuals" as the changes in air pressure are not what causes the attacks, and an indirect action of heat or cold cannot be demonstrated either. It would be more accurate to call them "electroscope" or "electrometer people," for there is much to sustain the assumption that there is a causal connection between the attacks and certain changes in the electrodynamic state of the air, such as is manifested in the so-called convection currents which accompany formation of rain, snow, hail, fog, etc. He adds that it may yet be possible to obtain some control over these currents in inhabited localities. Systematic research in this line may lay the foundations for study of the electric life of the cells, and when the time is ripe for this, there may develop a theory of electro-dynamics of which there are already glimmerings scattered through medical literature. The influenza epidemics point that way, as the assumption seems plausible that only atmospheric changes or something of that nature can explain the sudden acquiring of virulence the world around by ordinarily harmless saprophytes, or the sudden lowering of the resisting power against these saprophytes. Mygge suggests cooperative study along these lines by physicians and meteorologists.
